Über dieses Buch

Dies ist ein digitales Exemplar eines Buches, das seit Generationen in den Regalen der Bibliotheken aufbewahrt wurde, bevor es von Google im Rahmen eines Projekts, mit dem die Bücher dieser Welt online verfügbar gemacht werden sollen, sorgfältig gescannt wurde.

Das Buch hat das Urheberrecht überdauert und kann nun öffentlich zugänglich gemacht werden. Ein öffentlich zugängliches Buch ist ein Buch, das niemals Urheberrechten unterlag oder bei dem die Schutzfrist des Urheberrechts abgelaufen ist. Ob ein Buch öffentlich zugänglich ist, kann von Land zu Land unterschiedlich sein. Öffentlich zugängliche Bücher sind unser Tor zur Vergangenheit und stellen ein geschichtliches, kulturelles und wissenschaftliches Vermögen dar, das häufig nur schwierig zu entdecken ist.

Gebrauchsspuren, Anmerkungen und andere Randbemerkungen, die im Originalband enthalten sind, finden sich auch in dieser Datei – eine Erinnerung an die lange Reise, die das Buch vom Verleger zu einer Bibliothek und weiter zu Ihnen hinter sich gebracht hat.

Nutzungsrichtlinien

Google ist stolz, mit Bibliotheken in partnerschaftlicher Zusammenarbeit öffentlich zugängliches Material zu digitalisieren und einer breiten Masse zugänglich zu machen. Öffentlich zugängliche Bücher gehören der Öffentlichkeit, und wir sind nur ihre Hüter. Nichtsdestotrotz ist diese Arbeit kostspielig. Um diese Ressource weiterhin zur Verfügung stellen zu können, haben wir Schritte unternommen, um den Missbrauch durch kommerzielle Parteien zu verhindern. Dazu gehören technische Einschränkungen für automatisierte Abfragen.

Wir bitten Sie um Einhaltung folgender Richtlinien:

+ *Nutzung der Dateien zu nichtkommerziellen Zwecken* Wir haben Google Buchsuche für Endanwender konzipiert und möchten, dass Sie diese Dateien nur für persönliche, nichtkommerzielle Zwecke verwenden.
+ *Keine automatisierten Abfragen* Senden Sie keine automatisierten Abfragen irgendwelcher Art an das Google-System. Wenn Sie Recherchen über maschinelle Übersetzung, optische Zeichenerkennung oder andere Bereiche durchführen, in denen der Zugang zu Text in großen Mengen nützlich ist, wenden Sie sich bitte an uns. Wir fördern die Nutzung des öffentlich zugänglichen Materials für diese Zwecke und können Ihnen unter Umständen helfen.
+ *Beibehaltung von Google-Markenelementen* Das "Wasserzeichen" von Google, das Sie in jeder Datei finden, ist wichtig zur Information über dieses Projekt und hilft den Anwendern weiteres Material über Google Buchsuche zu finden. Bitte entfernen Sie das Wasserzeichen nicht.

CLINICAL NOTES AND OBSERVATIONS.

By Henry Lee,

Surgeon to St. George's Hospital.

I.—On Transplantation and Transmutation in Health and Disease.

As in some of the lower animals it may be shown that different segments possess independent vitality, so in the higher may it be demonstrated that every part has a life of its own, and that this life is capable of being maintained for a time independent of the rest of the system with which it is naturally associated. A portion of blood, for instance, may be taken from an animal, and after remaining separate for a short time, may be again infused, so as to remain part of the living organism.

Teeth, it is well known, have been transplanted in a similar way, as have also other parts of animal bodies. Such experiments clearly show that although incapable of continued separate and independent existence, each part may live when separated from the rest for a given time. Union implies reciprocal action. A dead part cannot unite with a living part. A tooth, therefore, which in its new relations shall adhere and grow, must have maintained its life when separated from its original bed, or a testicle removed from one animal and placed in the peritoneal cavity of another must in like manner, before it could have formed new adhesions and relations, have maintained for a short time its own independent life.

This subject has been abundantly illustrated of late by the transplantation of portions of skin. The number of instances in which this has been done of late have sufficiently proved that a portion of skin removed from the body has a life of its own, by means of which it unites with the part to which it is transferred. The life of the transplanted part is ultimately not less vigorous than that of the surrounding structures. In one case where two pieces of skin had been transferred to the surface of an old ulcer, the patient left the hospital before the ulcer was quite healed, and leading an irregular life, the ulcer again spread and became as large as it was originally. The transplanted portions of skin, however, retained their vitality when all the surrounding newly-formed skin had perished. In another case a portion of skin from a leg recently amputated was engrafted on a stump, where there was not sufficient skin to cover the extremities. Here a small portion only of the transplanted skin remained alive and adhered. In a third case where a large specific ulcer had existed for months, it healed to a certain extent under specific treatment, and then remained stationary. Some epithelium was now scraped off another part and allowed to fall and remain on the ulcer. Within a week a bridge of new skin had formed across the ulcer where the epithelium had been allowed to remain, while the rest of the ulcer was in the same condition as before.

The results of experiments like these are a great gain to surgery, and in order to derive the full benefit of them it is well that every precaution should be taken that no accidents should occur in their performance.

Now it must be borne in mind that where two living tissues unite, not their healthy, but also their unhealthy actions, have a reciprocal influence on each other. If a healthy action may be communicated, so may also a disease. This may be illustrated by the following cases:—

A young lady had a tooth transplanted, and it fastened extremely well. It continued firm for about a *month*, when the gum began to ulcerate, leaving the tooth and socket bare. The ulcer continued, and blotches appeared upon the skin, and ulcers also in the throat. The disease was treated as venereal, and the symptoms disappeared, but they recurred several times after very severe courses of mercury. She at last got well.

A gentleman had a tooth transplanted, and it remained without giving the least disturbance for about a *month*. The edge of the gum then began to ulcerate, and the ulceration went on until the tooth dropped out. Some time afterwards, spots appeared almost everywhere on the skin. He was put under a course of mercury and all disease disappeared. Some time after, the same appearance returned, with the addition of swelling in the bones of the metacarpus. He was now put under another course of mercury more severe than the former, and in the usual time all the symptoms again disappeared. Several months after, the same eruptions came out again, but not in so great a degree as before, and without any other attendant symptoms. He a third time took mercury, but it was only ten grains of corrosive sublimate in the whole, and he got quite well. The time between his first taking mercury and his being cured was a space of three years.

In the *Medical Transactions of the College of Physicians of London*, published in the year 1785, Dr. William Watson, at that time the vice-president of the Royal Society, gives an account of the case of a young unmarried lady, about twenty-one years of age, who had a tooth transplanted into the socket of one of the incisors of the upper jaw. The new tooth fastened exceedingly well. It remained firm for a month, when her mouth became very painful. The gum became ulcerated, and part of the alveolar process was left bare. Before another month, the ulceration occupied the whole space under the upper lip, between the teeth and nose. It extended likewise to the cheeks and throat. Blotches then appeared on her face, neck, and various parts of the body; several of these became ulcerated painful sores. After trying a variety of tonic medicines without benefit, two grains of calomel were ordered once or twice a day. She took about fourteen pills when she was obliged to discontinue the use of the calomel, on account of the griping and purging. During the time that she was taking the pills the ulceration of her mouth and cheeks did not spread, but was less painful, and of a milder appearance. The blotches on her face and body grew paler, and such of them as had ulcerated healed apace, and no new ones appeared. The mercurial inunction was now tried, but in ten or twelve days the griping and purging returned, and the ointment was discontinued.

The good effects of the mercury were, however, Dr. Watson observes, very apparent. The blotches all disappeared; the ulcerations in her face and body completely healed, and those of the mouth nearly so. A portion of the alveolar process subsequently exfoliated, and ultimately the patient died.

Thus, as mutual interchange of elements is essential to the continuance of existence, so may such interchange result in the communication of disease.

If a part ceases either to receive, for any length of time, supplies from other parts, or to give off from the body or back into the system those elements which are redundant, it dies. The means by which this mutual interchange is effected, in all the higher animals, is the circulation of the blood; the circulation then may be regarded as diffusing life through animal bodies, and the flowing blood may be looked upon as the life sustaining stream of the various organs of which those bodies are composed.

But as the blood-vessels are the means of conveying a life-diffusing energy to any part of the body, so may they be the means of carrying deadly influences; the stream which naturally is intended to support life, may itself contain the elements of death, the fatal influence may spread from the central and more vital organs to distant parts; or it may be communicated from any remote part to the centre, and thence again to the whole system. If the uniform and regular circulation of the blood through a part be requisite for its proper nourishment, it follows that any course which will obstruct that flow may interfere with its vitality; or if the return of the blood from a part be prevented, a similar result may follow. Considerable differences will occur in the local symptoms between cases arising from impeded arterial circulation and those in which the obstruction is in the veins, but a still greater difference will present itself in different cases according to the time occupied by the morbid process, which terminates in the death of the part.

Some surgeons of eminence have attributed much importance to the want of nervous influence in the production of mortification, we shall inquire how far this may be considered as one of the real causes of local death. The causes which induce separation, stagnation, and ultimately death of portions of the blood while in the living vessels, may, as far as these affections present themselves to the surgeon, be divided into three classes—namely, 1st, those which depend upon morbid deposit in the coats of the vessels, and subsequent discharge of that deposit into the current of the blood; 2nd, those which originate in a division of all the coats of a vessel, either from injury or ulceration, and the admission of diseased secretion from surrounding parts; 3rd, those which originate in some morbid action in the blood itself.

In the first of these divisions will be included diseases affecting principally the arteries, and in which the *materies morbi* is carried from the centre of the circulation towards the circumference; in the second will be considered principally diseases of the veins, in which the morbid products are, on the contrary, carried in the first instant from the more distant parts of the body towards the more central and vital organs; the third division is alike common to arteries and veins, and to the structure of organs which intervene between the terminal branches of each.

Majendie (*a*) from the experiments which he performed was induced to believe that fluids introduced into the arteries of animals, returned quickly through the corresponding veins, and that this occurred even more rapidly in the living than in the dead body. The experiments of Mr. Gaspard, however, show that while some fluids pass readily from the arterial to the venous system, that others do so with difficulty, and only after the lapse of a certain time; and it is probable that there may be others again which cannot do so at all, without previously undergoing certain changes. Some clear fluids, such as solution of tartar emetic, of opium, and of nux vomica, when introduced into an artery, pass readily in the course of the circulation, and produce their full effect upon the constitution. In such cases where the passage of the morbid matter is not opposed, little or no irritation is manifested in the capillaries through which they first pass. The first of the above-mentioned poisons produces vomiting and purging, the second, stupor, and the third, tetanic rigidity when injected into an artery, exactly in the same manner as if introduced into the stomach, or injected into a vein; but no great pain or loss of power is experienced in the limb upon which the experiment has been made. On the other hand, Mr. Gaspard found that when introduced into an artery the infusion of tobacco neither produced vomiting or purging, the solution of acetate of lead did not act upon the intestines, and putrid fluids did not produce those copious alvine evacuations which commonly follow the introduction of the same fluids into a serous cavity, or into the veins.

Fifteen grains of crystallised acetate of lead, dissolved without decomposition in rain-water, were injected (a third part at a time) into the crural artery of a large dog; each injection caused very great pain, the limb after the operation became completely paralytic, relaxed and cold; the pulse and respiration were frequent, and there was a good deal of thirst in the evening; the limb had swollen, but did not in the least recover its heat, its sensibility, nor its motion; the pain continued unabated. The animal died twelve hours after the experiment.

Post-mortem appearances.—All the organs in the interior of the body were healthy, but the limb was much swollen, emphysematous, and infiltrated with reddish serum; the muscles had become of a pulpy consistence, and of a reddish black colour; the lighter structures had assumed a violet colour, and the whole limb had the appearance of having been affected with gangrenous inflammation.

Four grains of tartar emetic dissolved in an ounce of water, were injected into the crural artery of a large dog, some pain was apparently experienced during this operation, and the animal walked a little lame upon the affected leg; from the time of the operation all food was refused, and violent retching and vomiting came on at the expiration of a quarter of an hour, much discomfort and restless-

---

(*a*) "Prices Elementaire de Physiologie," LII., p. 83

ness were now apparent; the pulse was small and feverish, but the limb, when handled, in no wise appeared preternaturally sensible (affording, in this respect, a strong contrast with the limb in the experiment last mentioned). An hour and a quarter after the operation, a kind of diarrhœa came on accompanied by a repetition of the vomiting, these symptoms recurred occasionally, until about three hours after the injection of the fluid, when the animal died.

Post-mortem appearances.—The limb upon which the experiment had been performed presented nothing unusual, the peritoneum was slightly injected, and contained some reddish serum; the stomach also was slightly injected, but only at its pyloric extremity; the mucous membrane of the duodenum throughout was livid of the colour of the lees of red wine, this appearance was continued into the jejunum, but the other portions of the alimentary canal were apparently healthy; the liver was congested and mottled upon its convex surface, in some situations its structure was so altered in consistence, as to break down upon very slight pressure; the gall bladder was healthy and full of bile, which was neither thick nor dark coloured; the lungs were studded here and there with a considerable number of petechial spots or small black patches.

In these experiments the injection of acetate of lead produced the signs of local inflammation in those parts to which the artery was distributed. The muscles which it supplied had become of the reddish black colour, and the whole limb had the appearance of having been affected with gangrenous inflammation. On the other hand, the introduction of tartar emetic in the same way produced slight local symptoms, but was followed by diarrhœa and fatal vomiting. Experiments like these clearly indicate that some extraneous substances when introduced into the blood expend their action by producing a local, although, perhaps, most severe disease; while others, which circulate more freely with the blood, will leave no trace of irritation in the first system of vessels through which they have passed, but will expend their influence upon some part to which their action is peculiarly determined, or will produce a constitutional affection.

◆

LECTURES ON THE TREATMENT OF CHRONIC SKIN DISEASES,

DELIVERED AT

ST. VINCENT'S HOSPITAL,

By E. D. Mapother, M.D., Professor R.C.S.;

Late Examiner in Surgery, Queen's University.

Lecture I.

You have seen so many cases of skin diseases during the past three months, sufficient to illustrate the most common forms of these affections, that I think it well to devote this and the following two lectures to their consideration from a point of view entirely clinical. In the arrangement of cases in this hospital, just as in the future practices of ninety-nine per cent. of you, there is little distinction between medicine and surgery; but if there is to be a separation, I claim skin diseases for the surgeon. They attack the external surface of the body; many of them depend on the venereal poison; some of them arise in the course of the treatment of surgical affections; and several require the surgeon's peculiar art for their cure, nævus, boils and some forms of lupus.

We will be able to study most of the diseases by cases in the wards, or amongst the out-patients, but if not, the beautiful portraits published by the Sydenham Society, or the smaller but no less accurate plates of Dr. Neligan, will aid us. As I was a pupil of that most able physician for four years, during six months of which I resided in Jervis-street Hospital, and selected many and saw all of the cases from which the drawings and photographs were made, I can vouch for their faithfulness.

I have always found that skin diseases were dreaded by students, and that if they were examined upon them in the various licensing bodies (which is too seldom the case), great ignorance was displayed. Students who have trained their ears to make out the most refined distinctions between the sounds of the heart or lungs, have neglected the education of those much more reliable organs, the eyes, even for the telling of acne from itch.

When we can apply all our senses to skin affections, our knowledge should be more exact, and our treatment less empirical than in the case of any other class of lesions. This ignorance, so much to be deplored, is due to their being considered a specialty. There is no more reason for having a lecturer on skin diseases in a college or hospital, than there is for a professor of the genito-urinary system, or professor of diseases of the chest, as is common in American schools. Professor Bennett, Mr. Hutchinson, and Dr. Neligan, are three good examples of men eminent in other branches of our science, who have added most largely to our knowledge of skin diseases.

Nor could I ever see the advantage of having these cases treated in a "Dispensary," or even "Hospital for Skin Diseases," or on only one day weekly in general hospitals. Why not let them be treated every day by the physicians, and, as I think should be, the surgeons of all our hospitals. The patients will at least be as well off, and the students will profit much more.

The classifications (or rather hair-splitting subdivisions) which specialists adopt have scared off scores of students, and I therefore propose to place in three groups certain diseases which are of common occurrence, of easy diagnosis, and of pretty certain, although not very rapid cure.

1st. Parasitic eruptions.

2nd. Moist eruptions.

3rd. Dry eruptions, and those which are due to systemic causes.

The first, which shall solely engage us to-day, are all contagious if the parasite finds a fit soil, and either caused by an animal or a vegetable enemy of the human body, the dermatozoa and dermatophyta, if you value and can remember classically derived terms. The oldest of these enemies, or at least that longest and most universally known, is the pediculus, or louse.

The species of that pest which prefers the hairy scalp is so common amongst the poor, or amongst the ill-cared children of the rich, that its intrusion has ceased to be regarded as a disease; it, however, usually points out that the blood of the patient is poor or unhealthy, and its irritation and abstraction of blood tend to lower strength still more.

Both the head louse, the body louse, and the pubis louse differ as you will see under these microscopes, but they are all apterous, or wingless insects.

The firm adherence of the ova of the head louse to the hairs is remarkable. These that you view under this microscope were not detached by scraping with the thumb-nail.

Although they thus differ they are not confined to the anatomical regions after which they are named. For instance, I lately treated a gentleman for a gonorrhœa, who at the same time was infested with pediculi pubis extending to his legs, chest, and arms, as he was covered to an unusual extent with hair. The pediculus pubis clutches most firmly to the hairs near their roots, and the symptoms caused by it are seldom quickly relieved. From the structure of its claws it finds it difficult to climb straight hairs, such as those of the head.

The pediculus corporis, or as it is more accurately called, pediculus vetis, for it holds closely by the clothes, is now believed to be the cause of that dreadful disease, prurigo, especially of the variety named senilis. This is after all a most satisfactory consideration, for we have potent means for stamping out so mean an enemy as that which causes this malady. Dr. Neligan and other writers ten years ago taught that the disease was often incurable. Such I have found it in out-patient practice, but we hope here for a speedy cure.

In our out-patients you often see scratches of all shapes, long if their nails be sharp, and rounder if they be strong and blunt, and these are wounds which patients suffering from prurigo involuntarily inflict on themselves. The temper of a patient will often determine the amount and character of the scratches. But you rarely or never see a pediculus on the skin. They lurk, by day at least, in the clothes. The skin assumes a peculiar pale or grey hue.

It has been said, since the days of the Emperor Arnulf, who has been stated to have thus lost his life, that they form subcutaneous burrows, but no scientific author verifies the popular belief. A nobleman of the highest rank in this city was believed to have been relieved by our great surgeon of the day having cut out such a tumour, but I find no account of the case in our medical literature.

Prurigo is often classed as a papular eruption, but it is without doubt due to pediculi, and with intense itching, no rash of any kind may be found. Hebra, however, states that a form of prurigo is quite unconnected with any parasites, and will endure during the patient's whole life, notwithstanding the most active and most varied treatment. His view of the etiology of prurigo may be gleaned from his words as follows:—"The drop of blastema exuded in a wrong place or in wrong quantity which composes the contents of a pruriginous papule will work as a constant irritant upon the nerves of the papilla, and thus produce a continual itching." Pruritis is said to be due to irritation of the erecting muscles of the hairs, and that, therefore, it will not occur in parts without hairs; but there are no more frequent sites than the mucous surfaces of the labia, prepuce, and rectum.

The scrotum, the pudenda, and the anal region are common seats of great itchiness or pruritus, due respectively to venereal excitement, pregnancy, and ascarides in the rectum. So they clearly are not mere skin diseases. The internal use of bromide of potassium or of bromide of iron, a preparation which I have recently used successfully in some cases of so-called spermatorrhœa, will allay the first. Bran stupes will check the second form, which, however, subsides in the later months of pregnancy. For ascarides I have found no remedy so useful as an enema of two ounces of carbolated oil (a drachm to the ounce) used every day at about the middle of the period between two defæcations.

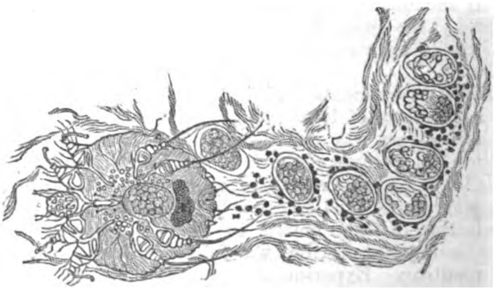
Sleeplessness is the only symptom for which internal treatment is needed, and twenty or thirty grains of hydrate of chloral in an ounce of water, with two drachms of syrup, is the fit draught to obviate this condition. In some cases, however, the sleep will be uneasy, and while they dream that they are brushing clothes, sweeping floors, &c., they will be really tearing their skin. Old people with prurigo often show an excited or despairing look, and mania has followed from the long-continued sleeplessness. Arsenic and a host of other remedies have been used, but without any result. So that the principle is to treat any functional derangement which may be present. Mercurial ointment will kill the lice, but getting into the scratches it often salivates. Carbolic acid ointment, with a small proportion of the former, is the safest parasiticide. It was in this hospital that my predecessor, Dr. Bellingham, first advised creasote ointment, twenty drops to the ounce of lard, for the cure of prurigo. A wash of two grains of bichloride of mercury to the half-pint of water is more cleanly.

The next most common animal parasitic disease is scabies—the itch. At present about five or six per cent. of the skin cases we see here are this malady. Dr. Fox states that in London it constitutes over fifteen per cent.; but according to Dr. McCall Anderson's statistics, out of 10,000 cases of skin diseases in Glasgow Dispensary, 2,527 were itch, and precisely the same number were eczema. The rash so peculiar to Scotland would seem to be a papular one, due to an irritation of the digestive mucous membrane by the husk of their oaten food.

Ten years ago itch was much more frequent in Dublin than now—a circumstance far more due to better diet spoiling the soil for the mite crop, than the cleanliness which I fear has not advanced amongst our poorer classes.

So constantly is this itch-mite (the acarus scabiei under this microscope) to be found in a burrow near the vesicle or pustule characteristic of the disease, that it is certainly its cause, as was stated by Aristotle, and with greater clearness by a lady who was formerly on the throne of France. Hebra says:—"The first indisputable reference to the acarus scabiei is in a work entitled 'Physika,' written in the twelfth century by St. Hildegard, the Lady Superior of the convent on the Ruperts-Berg, near Bingen."

After the mite has pierced the cuticle, it lays eggs in a burrow or cuniculus, and they take about a fortnight to hatch. Therefore, the disease generally arises ten days after infection. The burrow is here figured after Milbengang. The female survives about three months. When the eruption has been roughly treated or scratched, or in children where the cuticle is so thin, it is often hard to find the mite, but yet the doubts of French writers up to ten years ago about the causation of itch by this animal are absurd.



Hebra and most of the German naturalists regard the acari of the mange in dogs, cats, pigs, and other animals as identical with that of man; and Dr. Graves, in 1827, proved that children often contract itch from a mangy dog. The woman at present in St. Anne's ward asserts that she contracted the rash on her abdomen and thighs from dogs and pigs, which she cured of the mange. She is deceived, however, as the parasites which infest her (however she got them) are pediculi pubis. She was cured by carbolic ointment with one-eighth of mercurial ointment in a day, her clothes having been meanwhile disinfected at the hot-air chamber of the Corporation.

Wilson describes the sensation as "a kind of tickling, itching, and the rubbing and scratching employed to relieve it are said to be pleasurable. King James I. has the credit of having declared that none but kings and princes should have the itch, for the sensation of scratching was so delightful." From incautiously handling and hunting for the mite on a child's arms affected with itch in 1852, I contracted the disease on my hands. It did not spread, a fact which I might advance in proof of cleanliness, for among the dirty it spreads quickly. Few have had more to do with places in which zymotic diseases arose, but I have the satisfaction of stating that, with this exception, I never received or communicated contagion.

The itchiness is excessive, and is not always at the place where the acari abound. The regions where most scratches will be found are the abdomen and upper part of the thighs, although the legs, hands, and neck have more acari, and the eruptions they excite. If the rash appears on a palsied part, or in the person of a lunatic whose hands are confined, it runs a purely vesicular course, and none of the usual scratches can be found.

If a needle be thrust in, the female mite will cling to it, and it then will be found to be about 1-100th of an inch. The male is smaller and most difficult to find.

Itch has been placed under vesicular, papular, and pustular diseases, but these states are merely the result of an undoubted cause, together with varying proneness to pyogenesis, and all these kinds of eruptions usually co-exist. You have seen it on the hands, especially at the angles of the fingers, on the arms and legs, but very often near the inner ankle, never on the face. This immunity may be explained by the difficulty which the mite may experience in fixing there, as no clothes cover it. They most abound in warm places, where the clothes press; but it must be confessed this statement does not apply to the hands of the poor, which are ungloved and cold, by day at least. As warmth enlivens them, they spread to others sleeping under warm bed clothes. In children, and in ill-fed, delicate people, the acari and the disease multiply most, and the same may be said of all zymotic diseases.

The use of sulphur for the cure of itch is immemorial, and the ointment is the usual preparation given at dispensaries. When a few drops of oil of camomile are added to sulphur ointment it is best for all cases, "from the palace to the pig stye," says Wilson.

The most rapid mode of cure is described as follows by M. Hardy, of the Hôpital St. Louis, Paris, who regards it as infallible:—"On the admission of the patient the entire surface of the body is rubbed for half an hour with soft soap, he is then placed in a bath for an hour, the body well rubbed while in it, and at the end of that time general frictions are continued for half an hour with Helmerich's ointment (sulphur, ʒij, carbonate of potash, ʒj, lard ℥j.)."

I have found carbolic acid ointment most effectual, and that similar substance creosote has been long famous. Both of them destroy the ova as well as the acari. Petroleum is, I feel sure, a good parasiticide. In many military hospitals they use a wash made by boiling one part of quicklime, two of sulphur, and ten of water, until a full mixture is attained. After a bath this is well rubbed in, and when washed off the patient is cured, and he goes into new clothes, or the old ones disinfected. The mites have never had their breathing organs demonstrated, and some believe that the contact of air kills them. If so, bursting the vesicles ought to be enough for them.

What is really wanted for the cure of parasitic skin diseases in this city is a grand bath and disinfection establishment in connection with any hospital. It would be also available for treating the various cases in which the hot-air, or so-called Turkish Bath, is useful. An influential journal, the *Irish Times*, advocated the erection of a free Turkish Bath, and subscriptions were freely promised. I think it likely that the Sisters of Charity, ever anxious to promote the interests of the sick poor, will endeavour to erect such an establishment on these very grounds. If they do, or if such an establishment is to be erected and maintained by public subscription, I will willingly bear a considerable part of the expenses. If they were open only twice weekly, one day for females and another for males, the cost of fuel would not be great.

The following is a description of the baths at the University College Hospital, London, which owe their origin to the energy of my friend, Dr. Tilbury Fox:—

> They are cemented throughout, as paint would be discoloured by the chemical vapours employed. The itch bath holds two or three patients at once. Soap is first applied freely, then sulphur and potash ointment is left on for twenty minutes, and lastly comes a thorough washing. Adjoining this room is the disinfecting chamber, and from it all the vapours from the articles pass through the fire. Itch mites, lice, and their ova lodge in clothes, and are here quickly killed, while the parasites are being destroyed on the skin.
>
> In the Turkish Bath fire tiles are used, as iron robs the air of oxygen quickly, and fresh air is most freely admitted. There are also hot water and steam baths, with comfortable dressing-rooms (*a*). The cost for this building has been only £1,500.

Now in such a place prurigo, which is often regarded as incurable, and which every dispensary attendant will allow haunts him for years, may be cured in a couple of hours. So may itch, and herpes of the scalp, and ringworm of the body, may be cured in a very short time.

As these affections form a vast proportion of the skin diseases of the poor, such an establishment would be an unequalled boon. It might be made available for out-patients as at the St. Louis Hospital, Paris, for the cure is so rapid that they need not have beds, and the admission of parasitic cases disgusts other patients, and renders them liable to them.

Messrs. Frazer, Commercial road, London, have patented a good apparatus for disinfection by heat, which is moderate in price, some £150, I believe.

The vegetable diseases of the skin, or dermatophytæ, are named in the Nosology of the London College of Physicians, Tineæ. Now the word originally means an moth, and is therefore inapplicable to these affections, but I am so much averse to the multiplication and change of names of skin diseases, I shall adopt it as descriptive of all those attributable to vegetable growths. The following are sufficiently common to merit your attention:—1. Tinea favosa. 2. Tinea circinata. 3. Tinea menti; and 4. Tinea versicolor.

No one who attentively reads the arguments of Dr. Bennett, the great Edinburgh physiologist, can doubt that cryptogams are the positive cause of these affections.

These epiphytic growths are most easily reared on the soil which the young body offers, a circumstance common as well to epidemic and epizootic diseases. Fish reared in aquariums are very prone to a somewhat similar fungus, the *achlea prolifera*, which attacks the skin and gills, and thus died the eyeless fish of the Mammoth Cave of Kentucky in our Zoological Gardens four or five months after I had taken them from their wonderful birth-place.

From the water of our baths or the fluids we drink, especially those fermented, it is possible we may imbibe fungi. If our Government supported original scientific research as fully as is done in German States, many diseases of which the origin is now obscure would be soon understood.

Many microscopists regard the fungi which are found in the above and many other tineæ as one and the same, only varying according to soil on which they grow. The fungus of favus is most strikingly like the oidium lactis, the plant growing on sugar of milk. If the plant of favus on the scalp and ringworm on the body be the same, the greater vascularity and abundance of sebaceous glands of the former place accounts for the more free discharge of a semi-purulent matter. Dr. Purser has shown that a case of ringworm, tinea circinata, was contracted from favus on a cat. They spread from the opening of the hair follicle downwards to the root and papilla, and this affords evidence of their being derived from without, and not any epithelial growth. The false hair used in chignons must be well cleansed, for scalp parasitic ailments have not sensibly increased since their introduction into fashion.

Their parasitic nature is most satisfactorily shown by the fact that removal or destruction of the microscopic object secures the complete cure of the disease.

Persons living in damp places or cellars where bread becomes quickly mouldy are believed to be peculiarly liable to these vegetable diseases. Habitual bathing is an all-efficient preventive for this and many other ills.

Tinea favosa, or true scall-head, as it is often called, occurred 156 times in 10,000 at the Glasgow Dispensary, and four times in 1,000 of Dr. Anderson's private cases. On the Continent the brothers Mahon treated 40,000 cases in twenty years. It is now rare in Dublin. About the year 1850 I saw many cases, about twenty, amongst the poor, especially those from remote rural

---

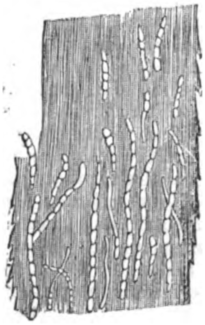
(*a*) A full description and plan were published in this Journal, Aug. 1871.

districts, and the terribly low diet of the five previous years, may have produced very fit soil for its growth. It is nearly always found in children from four to twelve years of age.

The sulphur-yellow concave crusts, about two lines in diameter on the head, or thrice that on the body, fully characterise the disease. In the beginning such cups are scattered, but they soon coalesce, and out of each a hair springs, for the parasite always has root in the hair follicle. The pressure of the cups produce depressions in the cutis of a slightly concave form. Itchiness is present, and as the children scratch the head it may be thus spread to other parts of the body. Baldness results after a while in the part of the scalp first infested, and it is very difficult of cure.

Pediculi soon invade the head, and the crusts give out a vile smell like that from mice. These animals often develope the achorion, and man may have been originally infected from them.

The fungus which, with scarcely a doubt, causes this malady was discovered by Schonlein, and by him was named Achorion. Under this microscope you will see an admirable specimen, showing the oval cellular spores, single or jointed, and the filaments of which this crytogamic plant consists. The spores are about the size of our blood cells, and thus over twice the size of the next plant we have to mention. This figure, from Neumann's great work translated by Dr. Pullar, shows an infested hair. That the inoculation of the plant into a healthy skin will produce the disease, has been proven most conclusively by Gruby, Professor Bennett, of Edinburgh, and Dr. Walter Smith. Every person cannot be infected, and it would seem to thrive only on the ill-fed, who are subject to other zymotic diseases. For every contagion there must be a specially prepared soil. As regards treatment, the great principle constitutionally is to change diet, and as the underfed are usually the victims, plenty of milk, eggs, and meat, with pure air, bathing, and exercise, to give appetite for them, aid wonderfully the local means of killing the fungus. This is accomplished by clipping the hair and keeping the whole surface soaked with one to two drachms of sulphurous acid to the ounce of water, first suggested by Graham, the great chemist; or bichloride of mercury, two grains to the ounce. I would believe more in a solution of one drachm of carbolic acid in an ounce of alcohol, diluted with half a pint of water, but I have had no opportunity of trying it, for the disease has been very rare. In severer cases the hairs must be chucked out with a broad-pointed forceps or tweezers, and after this epilation (I must teach you technical words), the sulphurous acid solution of the "Pharmacopœia" should be painted into the follicle with a small pointed brush. The French dermatologists cure it, they say, at a single sitting.



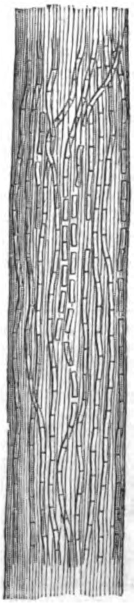
Dr. Neligan, who treated nearly all the cases I have seen, gave for many weeks the following pills:—℞ arsen. iodid. gr. ij., mannæ, gr. xij.; mucilag. q. s. ut fiant pil. xxiv. "One thrice daily."

Such medicines should, of course, not be ordered unless you can see your patient two or three times weekly.

If considerable baldness remains after a month or two, the cantharides pomade (one to two drachms of the tincture to the ounce of lard, properly scented) will promote the growth of hair again.

The disease of man's shaven chin and cheeks, named sycosis, from the likeness to the interior of a fig, is believed by many to be a form of tinea favosa, by others a kind of acne. Having very rarely seen the affection, I will not venture to make any remarks about it, the more so as the memory of a case I saw with Dr. Neligan, where a gentleman, notwithstanding the advice of all the authorities in Europe, had laboured under it for twenty years, impresses me with the intractable nature of the affection.

Ringworm of the scalp and of the body (tinea tonsurans and circinata) is the next vegetal disease we shall to-day study. The plant which excites it is named the *tricho-phyton tonsurans*, and inoculation with it readily produces the scalp eruption. I showed you an excellent specimen magnified by a ¼-inch object glass. This figure, from Neumann shows a hair attacked by tricophyton. Children, young, but of all constitutions, suffer from it. As Dr. Frazer has well worked out, calves are often attacked by the tricophyton and it is from them often spread to children.



On the scalp it stunts the hairs and renders them so dry and brittle that they break off near the scalp for the most part in round patches as implied by the name.

If there be doubt as to the nature of the case the microscope very readily dispels it. Prof. Wilson regards ringworm as only catching in a school when the children "are packed together too closely, to the deprivation of proper ventilation; there must be error of diet, air, and exercise." In this I cannot concur, for I have lately attended in a high-class school, managed most carefully, and found that twenty cases of ringworm had spread from a single one, that of a new boarder.

One form of eczema, that called marginatum, is said by many German microscopists to be due to the tricophyton, and Neumann states that by careful culture it will develop into the well known and widely diffused fungus pencillium glaucum. From its clinical character I would regard it as ringworm, which heat and moisture had rendered more prolific. As the horse is often affected with tricophyton its extension to grooms is not to be wondered at.

The great principle of treatment is to remove the affected hairs along which the fungus grows below the surface of the skin, and to cut short those around.

The hairs and cuticle are to be softened by washing with soft soap which may be left on for a few hours.

Now, carbolic acid kills the fungus effectually. It should be first applied diluted with three or four parts of alcohol round the circles with a camel hair brush.

Iodine dissolved in carbolic acid (such as that prepared by Evans, of Dawson street) is a useful application. The attendant should take care that he does not contract the disease on the hands.

No internal remedy is required unless there be any diseased condition beyond the cutaneous one, and then it will be indicated according to general therapeutical principles.

That very common disease tinea of the body or as it is more frequently called, herpes circinatus is attended by the same parasite as that last mentioned, and the two are often seen combined.

Its spreading circles leaving the centre healthy makes the diagnosis of the disease easy. I have very rarely seen the newest ring show the vesicles even under a strong magnifying glass. If ringworm shows a striking variety of tint in the patch it is called herpes iris a very rare disease, according to Dr. Neligan, but nearly twice as frequent as herpes circinatus, according to Dr. Damon in the "Boston City Hospital Reports." Such discrepancies arise from want of accurate definitions of the disease.

The exposed parts of the body, face, neck, and forearms, are the most common sites.

The treatment should be wholly local, and the best parasiticide is carbolic acid or sulphurous acid.

A solution of cyanide of potassium will also kill the fungus if fairly and constantly applied.

Tinea versicolor is often regarded as a form of pityriasis from which we shall afterwards see it differs essentially.

It occurs in large patches of a greenish brown often on the chest and other heated parts of consumptive patients, most frequently those who wear flannel and allow the perspiration to dry. The most extensive case I ever saw was in the person of a lady who, although healthy, overclothed herself and over heated her bedroom to a degree which might have caused her to be adjudged a monomaniac on the point. There is a good deal of itching, which, however, the very first bath removes; on the under surface of the cuticular scales which come off freely there are spores and threads of the microsporon furfur about 1-7,000th of an inch in diameter. Dr. Anderson has proved its contagious nature, but it spreads much less than other dermatophytes. It was very common during the Irish famine, when the potatoes were suffering from a foreign disease.

It is said to have been mistaken for the stains left by venereal eruptions or for those patches where the melanin of the skin being absent the term leucoderma is applied, a kind of partial albinism.

The cure is easy; when the patches are washed well with common soap to remove the oily and sweaty matters, a wash of 1 oz. of hyposulphite of soda to 12 oz. of water is very effectual.

Mr. Rivington accidentally discovered that a solution of cyanide of potassium five grains to the ounce such as photographers use will quickly kill the fungus.

I may here mention that other forms of pityriasis are merely increased scaliness of the skin. Frequent baths and hard rubbings after will quickly remove the condition, and shampooing of the scalp will check the formation of dandriff there

CLINICAL MEMORANDA.

(Reported by John W. Martin, M.D., MCh.

Assistant-Surgeon to the Mayfield Factory Dispensary, and late Assistant-Surgeon to the North Tipperary Light Infantry Militia.

In publishing the following three cases, in addition to the series which have already appeared in the pages of the Medical Press and Circular, as illustrations of the marked benefit frequently to be derived from the hypodermic method of administering morphia, I do so, not from any special importance attached to the cases themselves, but merely, as further examples of the utility and reliableness of this treatment. To the busy practitioner, a useful hint may often be derived from such records, provided they are the result of careful and truthful observation.

I am well aware that the subcutaneous administration of medicines has firmly established itself in the favourable consideration of the members of our profession, but I am impressed with the idea, that much remains to be done, in the way of recording clinical experiences of its utility, and the conditions in which its favourable action may be expected. I would throw out as a suggestion to any competent to undertake the duty, that a most useful little work might be produced by a careful compilation, and digest of clinical records on the subject, and a concise tabulation of the conditions which would indicate a resort to it. The first case that I have to offer, is that of,

Patrick Foley, groom, æt. thirty-five.—For a long time he has been unaccustomed to walking any long distance. On the 17th of September, he had to walk over twenty miles to transact some business. On the 18th, the day following, he felt such severe pains in and from the small of the back and hips, down the legs and feet, that he was unable to return to work, and remained at home in bed all day. Again made a fruitless attempt to return to work on the 19th, the date of my visiting him. I found him restless and feverish, having got no sleep or rest during the preceding night, pulse quick; tongue furred and dirty; and feeling wearied out and fatigued. I injected according to my usual plan as before described, $\frac{1}{4}$ grain of morphia. In *five minutes* after the completion of the operation, the pain subsided almost entirely. He felt the usual warm glow run down and up his arm, and thence through his whole body, but no unpleasant sensation.

September 20th, 1861.—Passed a good night, with the exception of slight uneasiness about the anterior surface of the tibia; he was free from all pain or fatigue, and was able to resume work.

Case II.—John Ryan, labourer, æt. thirty-one.—(Notes taken September 21st, 1871.) This patient first came under my notice on September 14th, 1871, previous to which for the past six years, with but few intervals of ease, he has been a martyr to severe sciatica, along the course of the left sciatic nerve. He had been under the care of various medical men, in and out of hospital, and had undergone a regular course of all the most approved methods of treating this intractable disease, both by counter-irritation in all its forms, anodyne liniments and tonic constitutional treatment. After a three weeks' stay in hospital, about six months previous to my seeing him, he obtained a slight temporary relief to the pain, which for the past twelve months, was growing more severe and constant. Just previous, however, to my seeing him, the pain was becoming unbearable, rendering it impossible for him to proceed with his usual avocations. Every other means having failed to procure relief, I at once determined to give him the full benefit of the hypodermic treatment, and fortunately with complete success. I first injected a quarter of a grain of morphia over the upper portion of the nerve, the operation being followed by immediate ease to the parts. The good effects of this injection lasted two days, during which time he was able to move about freely, in marked contrast to the agony that motion produced previous to his visiting me. At the end of that time, a slight pain making itself felt in the upper part of the popliteal space, my father repeated the injections, using this time, however, three-fourths of a grain. On Nov. 23rd, 1871, he called to report his complete recovery to us, stating that since the last administration of the morphia, he never had the slightest return of the pain, and that he had been able to undertake the heaviest duties of a farm labourer. He looked the picture of robust health, and expressed the liveliest gratitude for the benefit received.

CASE III.—John Morris, æt. fifty-five, labourer.—(Notes taken September 21st, 1871.) This man's case is so much a repetition of the last, that it will be unnecessary for me to enter into it at length. Suffering from a sharp attack of sciatica, for which ordinary remedies failed to obtain relief, I injected him over the course of the sciatic nerve to the extent of a quarter of a grain, relief being immediate. Next day he felt so well, that he attempted to resume work, but the day being raw and wet, the pain returned, and forced him to desist. I again threw in a quarter of a grain, and ordered him to lie by for a few days, with the result of his permanent cure.

◆

UTERINE NEURALGIA AND ITS CHIEF COMPLICATIONS:

THEIR PATHOLOGY AND TREATMENT.

By JOHN CHAPMAN, M.D., M.R.C.P., M.R.C.S.,

Physician to the Farringdon Dispensary.

Uterine Neuralgia (Hysteralgia, Irritable Uterus).—Painful affections of the womb, unassociated with what is called "organic" disease, are very common, and have attracted a large share of professional attention. Since Dr. Gooch's famous discovery and description of the "irritable uterus," this troublesome and often, hitherto, intractable malady has obtained general recognition as one of the most notable among the many diseases to which women are liable. As rightly observed by Dr. Ashwell,—"A narrative of the symptoms of painful menstruation, in its neuralgic form, would, with slight alterations, suffice for irritable uterus," as first described by Dr. Gooch. In fact, those sufferers from difficult and painful menstruation, who also suffer from uterine pain in a more or less subdued form during the menstrual intervals, are victims of "irritable uterus." It is most frequently observable in women above twenty-five years of age, and occurs probably quite as often in married as in unmarried women. Pregnancy rarely happens during its continuance, and it is especially prevalent during the closing years of the menstrual epoch.

The pain may be correctly described as lumbo-uterine; for while it generally spreads across the lower part of the back, and around the pelvis, and not unfrequently extends along the thighs even to the knees, its chief and permanent seats are the lower third of the spinal cord, and the part of the abdomen immediately above the pubis. In almost every case the pain is extremely intense, and in many cases is a perfect agony, during the menstrual periods. In the intervals, the pain, though generally subdued and tolerable, is capable of being excited to a surprising extent by slight causes, such, for example, as walking, riding, going up stairs, the jolting of a carriage, or mental emotion; and, in very severe cases, merely sitting up, or standing for a short time, will induce a sudden access of pain. I have frequently known it to be brought on by the act of defæcation, and even by that of micturition.

Besides these symptoms which are most commonly met with, several others are frequently associated with uterine neuralgia. Among them, and especially characteristic, is a group of phenomena closely resembling those of inflammation in what is commonly called its chronic form: there is marked tenderness evinced by pressure over the hypogastric region; examination *per vaginam* is often almost impracticable, and pressure on the mouth of the womb will probably prove so intensely painful as to cause the patient to shriek; more or less throbbing, a certain sense of fulness and of heat beyond the normal degree is experienced, and, if the speculum be used, the cervix uteri is seen to be somewhat tumid or puffy, and redder than natural. There is also, hyperæsthesia and tendency to spasm, of the vagina, in a considerable portion of cases; coition, if at all bearable, is attended with great pain. Leucorrhœa is a remarkably constant concomitant, the quantity and quality of the discharge being, however, very variable; the catamenia are generally deficient in quantity—they usually recur irregularly, are most frequently retarded, and, when present, are apt to be intermittent. In very severe cases, a false membrane sometimes forming, when passed entire, a fairly accurate cast of the interior of the womb, is discharged. Sometimes this membrane is passed in fragments, and much time elapses, and intense suffering is experienced, before it is wholly got rid of; and, in some cases, evidence seems to show that, within a very short period, two or more membranous exudations occur in succession. Bearing-down pains and a sense of weight in the pelvis are very commonly complained of; the womb generally sinks down, more or less, into the vagina, and in a considerable portion of cases *prolapsus uteri* is a pronounced symptom. Extremely troublesome frequency of micturition is very common, the urine being generally copious and pale, but sometimes decidedly high coloured, and occasionally having a strong characteristic odour. There is often considerable derangement of the digestive function: the appetite is apt to be capricious, and nausea, or even vomiting, not unfrequently occurs. The bowels are generally constipated, and flatulence, often to a very distressing extent, is a prominent symptom. The anus is apt to be spasmodically constricted. The peripheral circulation is often astonishingly irregular, a condition manifesting itself by alternate shiverings and flushings, by headache, feverishness at night, and, of course, unrefreshing sleep. If the disorder has existed a considerable time, the physician may confidently predict the existence of great tenderness of the spine, especially along its lumbar and lower dorsal segments—tenderness which will be quickly manifested if slight pressure be made upon it, and which is often accompanied by tenderness along the whole spine, but especially between the scapulæ, and by general hyperæsthesia of the spinal region.

In the foregoing description I have attempted to represent as accurately as I can, within the brief space prescribed to myself, a typical case of "irritable uterus," but such cases are less frequently met with than those forms of uterine neuralgia in which the phenomena of inflammation, or resembling those of inflammation, are not observable. In these more ordinary cases, a more or less abiding sense of painful bearing-down during the intervals of the catamenia is the principal evil complained of, the other symptoms being similar in natureto that of those just described, but manifesting themselves in less pronounced forms. Moreover, of course, some of them only are present in one case, some in another; and though the menses are, as a rule, irregular and deficient, some cases occur in which they are almost continuous, but slight, and some also present themselves in which menorrhagia, accompanied by marked pallor and anæmia, proves a serious complication. Sometimes the menstrual discharge is inducible at almost any period by various and very slight causes. Dr. Lee says,—"If the disease continues long, and the powers of the system are much impaired, it is entirely interrupted."(a) I have met with no case of uterine neuralgia in which menstruation was wholly absent, but I have met with cases in which there was no leucorrhœa. Constipation of the bowels so generally present, may be replaced by chronic diarrhœa, and not unfrequently the two disorders alternate with each other. Occasionally, uterine neuralgia may come on by transference from some other part. Dr. Tyler Smith has mentioned a case published by Dr. Handfield Jones,(b) "in which frontal neuralgia and ague continue until puberty, and were then replaced by 'irritable uterus.'" Of course, the malady very often occurs as a result of reflex action.

ON THE TREATMENT OF SCIATICA
BY THE
VOLTAIC CURRENT OF ELECTRICITY.

By Wm. Stephenson, M.D., F.R.C.S.Ed.,
Lecturer on Diseases of Children, and Physician Royal Hospital for Sick Children, Edinburgh.

The following two cases of sciatica treated by the voltaic current ot electricity, illustrate well the action of the agent in the treatment of néuralgic pain—a subject which is attracting considerable attention.

By the Voltaic current is meant one derived directly from a battery, and distinguished as the primary and continuous current; in contradistinction to that in general use, the Faradic, induced, or secondary, obtained from an induction coil or magneto-electric machine. The latter is a momentary current more or less rapidly repeated. The distinction must be constantly kept in view, for they differ much in their physiological and therapeutic action, and as I shall presently show the Voltaic has much greater effect in relieving and curing pain than the Faradic:—

Case I.—David L——, æt. thirty-four, a carter, states that twelve months ago he had a fracture of the tibia for which he was treated in the Infirmary. Ever since he has had a pain in the outer part of the leg and foot. Eight months ago it extended to the hip over the sciatic nerve, and he has since been quite lame. The pain is easy while sitting but severe whenever he attempts to walk; he cannot stand erect; while in bed, if he moves his leg, he feels unable again to get it into an easy position, and has to get up often during the night on account of the pain. He has always enjoyed good health and has never had rheumatism. He has been attending the Royal Infirmary, where he has been purged, has taken quinine largely, needles were introduced, blisters applied, and twice he has been cauterised with Corrigan's button, but all without benefit.

Dec. 7th, 1870.—A current from ten increased to twenty cells (Daniell's) was applied for five minutes, by means of moist sponge conductors, the positive pole being placed over the sacrum and ischiatic notch, the negative at various points along the course of the nerve. He stated that he felt greatly relieved, but the pain was not entirely away.

Dec. 8th.—He walked home with greater ease than before; could stand straighter up; he has had a better night's rest than since the pain began. Fifteen cells were again applied as before.

Dec. 9th.—Walked home quite free from pain; slept well; found a slight pain in the leg in the morning when he rose, but passed off when he began to move about. Fifteen cells as before.

Dec. 10th.—Had a good night's rest; was able to take a walk to-day; can stand perfectly erect. Twenty cells direct and inverse current for fifteen minutes.

The application was continued regularly and the improvement maintained. There was still, however, a residue of pain which remained obstinate, and was always induced when he walked much, or if the treatment was interrupted. The affection was worse in frosty weather. The effect of the induced current was tried for a time by means of a magneto-electric machine. It at once relieved the pain, like the other, but the effect always passed off much sooner. The subcutaneous injection of morphia was next combined with the voltaic treatment. This produced a more decided effect, but the pain continued to return after a day's walking. Iodide of potass, quinine and arsenic were given, and for three months, with one or two interruptions, the electric treatment was persevered in. The patient indeed was always glad to return on account of the comfort he experienced. The strength and direction of the current and mode and duration of application were modified as much as possible, without any change. It then occurred to me to try the electro-puncture, an insulated needle being introduced into the hip near the nerve, and a moist sponge applied over the painful spots in the leg. The effect was decided, a steady and continuous improvement being felt after each application, and after the sixth all residue of the pain was removed.

Case II.—David O., æt. fifty, a letter-carrier, has suffered from sciatica for four months, never had rheumatism, but once had lumbago. The pain extends over the whole length of the nerve, and affects also the superficial sacral nerves, it is always worse at night, and greatly interferes with sleep. He has been blistered seven times, four times had acupuncture applied, and taken several medicines. From the acupuncture he derived some benefit but the pain always returned.

The electricity was applied, and benefiting from the experience of the former case the electro-puncture was used at once. The relief after the third application was decided, but the returns of the pain after walking were at first severe and frequent—but never lasting long. Whatever pain he had was always at once removed by the application. In a fortnight he could walk about freely, but it was not until after five weeks use that the last residue was removed and he was able to resume his employment.

In using the electro-puncture a much feebler current is required than when the resistance of the skin has to be overcome. I had several opportunities also of observing in the latter case that when too strong a current was used, or the needle applied too close to the nerve, there was sure to be an exacerbation of the pain during the night. Five cells produced the best results; ten seemed to overstimulate and fifteen excited the pain at the time.

I have treated five other cases with the current. Two were recent cases, and had not been otherwise treated; both were well in a fortnight. One was the mild but persistent "residue" of a former attack and was removed in a week. The other two were much relieved but left for the country after a few applications only.

In all an immediate relief was experienced, and this is the great criterion whether the case is likely to be cured or not. If no relief is felt after three or four applications there is little probability of any benefit. The progress to perfect cure may be slow—the above, from the experience of others, are exceptionally so—but the severity of the affection is broken at once and comparative comfort is gained. The first case was protracted. but all the more instructive, giving an opportunity of testing the relative merits of the two currents, and illustrating how much the want of success may depend not upon the remedy but the mode of its application.

◆

Hospital Reports.

KING'S COLLEGE HOSPITAL.

Hernia—Wood's operation—Clinical Remarks and Statistics—Varicocele, treated by Wood's Mouse-trap Spring—Clinical Remarks—Abscess under Temporal Fascia—Remarks.

(Under the care of Professor Wood, F.R.S.)

The case of hernia was in a little boy, who having been placed under chloroform, the Professor proceeded to perform the operation he had introduced to the profession, and which was now so well-known throughout Europe as Wood's operation. After its completion—Professor Wood—on account of a number of strangers being present, obligingly gave a short but very clear account of the several steps of the operation. Without, however, following the learned lecturer in his interesting description, we think the subjoined remarks worthy of record, inasmuch as we believe they are not at present to be found in any system or manual of surgery. When introducing the wire, the Professor observed that in his early cases, he had frequently been baffled, on account of the incision made through the various tissues not corresponding after the needle armed with the wire had been introduced. He now, however, met with no difficulty, as he pushed the needle through with a sort of jerk, so that the wire almost preceded the needle, and consequently there was not time for the apertures through tissues, to be placed at irregular levels. As regarded the success of the operation, Professor Wood stated that he had operated on 200 cases or thereabouts—about 70 to 75 per cent. had been successful—the majority of the cases had been performed in the theatre of King's College Hospital, in the presence of surgeons from all parts of the world. There had only been two deaths—these were in hospital patients—one from pyæmia—a hospital disese—the other from peritonitis, but this was secondary, as the *post-mortem* showed no signs of peritonitis whatever in the parts that had been operated upon. In private practice, he had had no deaths. The unsuccessful cases were as a rule in young children, in whom the hernia was large. Two and sometimes three operations were necessary in such cases. He believed this was due from the fact of the parts being much more relaxed, together with the low vitality of the sac and its circulation.

The case of varicocele was performed by the Professor, by subcutaneously tying the vein and then fixing the ends of the wire to the spring of the miniature spring écraseur, an instrument devised by himself. The advantages of this instrument were the steady equable pressure of the spring, which gradually dragged the suture away, seconding therefore the ulcerative process. The great objection to all previous inventions was the necessity of a second screwing, and this was the objection to the instrument Professor Wood had previously introduced, as also to that of Ricord. The operation it must be remembered, was *une operation de complaisance*, consequently it was the bounden duty of every surgeon to avoid giving as little pain as possible. The instrument was very simple, it was made on the principle of the mouse-trap spring. It should be remembered, that not only did the "*second or screwing operation*" give excruciating pain to the patient, but that also there was the danger of inflammation and suppuration. In a case previously operated upon by him, to which the attention of the class was now drawn, they would see how little disturbance there was from the normal condition of the parts, and that the scrotum felt cool and comfortable by the use of this instrument.

In conclusion, Professor Wood maintained that in such operations, *the desideratum* was to keep such tension on the wire around the vein as to draw it gradually off. Secondly, that in coming off it should not twist the vein. Thirdly, this if accomplished would avoid he believed anything like suppuration.

The attention of the class was then drawn to a case of abscess under the temporal fascia, in which the matter was making its way through several small apertures in a semicircle corresponding to the marginal attachments of the temporal fascia. Cases of this kind, the Professor observed were sometimes difficult to diagnose, as for instance, when the matter following the insertion of the temporal muscle opens on the inside of the mouth. Again, the disease when it spreads as far down as the tympanum—the matter—as had been pointed out by the late Mr. Toynbee, following the course of the superior petiosal sinus, found its way by the lateral sinus into, and there set up inflammation of the brain.

EPIDEMIOLOGICAL SOCIETY.

WEDNESDAY, 13TH DECEMBER, 1871.

ROBERT LAWSON, ESQ., F.R.C.S., President in the Chair.

MR. W. D. MITCHELL read a paper on "the Outbreak of 'Spring' Cholera at St. Petersburg, the History and Progress of the Epidemic through European Russia in 1871." The chief points of interest with regard to this epidemic were brought before the society, illustrated by charts, showing at a glance the march of the cholera and the degree of intensity with which it prevailed in the several governments of European Russia. The whole of the official returns, so far as yet published, were also shown, arranged and tabulated according to the various governments, giving averages of mortality per 1,000 of deaths to cases (or attacks), and of per centage of cases to population. The census returns quoted were those of 1870, just published at St. Petersburg, together with the meteorological and other tables. The comparative method should be always used by way of crucial test in all epidemiological study; one should never rely solely upon either the pathological, physico-chemical, statistical or meteorological aspects of the question.

The co-incident phenomena or favouring conditions observed at the local "spring" outbreak at St. Petersburg with tables of disease, statistics arranged in daily and in weekly periods, showing its "epidemic vital force," were then reviewed in detail.

The *Summer Heat Diarrhœa* should always be eliminated, being entirely distinct from epidemic Asiatic cholera. The relation and connection between an epidemic of enteric fever already existing over a defined area, with that of an invading wave of cholera, with their correlation and influence, on each other, as met with in other zymotic diseases; and the prevalence in 1871 and previous years of epizootic and epipyhytic diseases in Russia were then succinctly treated.

The other points brought forward were:—

The rapidity and almost day-coincidence in point of time with which the cholera appeared at different place in so wide an area as European Russia. On this head remarkable facts were brought out clearly by chronological and geographical charts of epidemic cholera, not only in Russia, but also in India, Persia, Zanzibar, &c.

Its apparent localisation, as at Kieff since 1868; thus waiting for the next and succeeding years before vitalising into its epidemic and spreading—form frequent proofs of this.

The condensation, over-crowding, and the insanitary condition of inhabitants, either in town or country, always found to be a constant factor and to exert a vast and overwhelming influence on the existence, spread, and death rate of cholera.

Cholera has not this year lived or become vitalised in any of our ports. Important questions for the epidemiologist to consider are: Will it behave in like manner in 1872? Or will there be "spring-cholera" in 1872 in Northern Europe? Is there a "a wave of typhoid" in advance of it? Will this direct, influence, or modify in any degree the progress of cholera westward?

SATURDAY, DECEMBER 16TH.

MITRAL CONSTRICTION—DEATH—AUTOPSY.

DR. HAYDEN exhibited the thoracic viscera of a boy, æt. eighteen years, who died in the Mater Misericordiæ Hospital on the preceding day. Four years ago, the boy, then fourteen, was first admitted under Dr. Hayden, suffering from angina and collapse. Constriction of the mitral orifice was then diagnosed from the existence of the pathognomonic presystolic murmur at the apex of the heart. One year previously, the boy had been thrown from a pony and trodden on by the animal, after which he spat some blood and suffered from dyspnœa. Eight months subsequently he began to suffer from angina, which recurred at uncertain intervals, and in one of these attacks of unwonted severity, he sank down in the street and was conveyed to the Mater Misericordiæ Hospital. Beyond the cardiac lesion nothing of interest was detectable. The boy improved under treatment, and was able to leave hospital at the end of a month and resume his duties as a light porter. Within the succeeding four years, he was re-admitted under Dr. Hayden twelve different times, suffering from intercurrent attacks of hæmoptysis, bronchitis, or angina and thus an ample opportunity was afforded of following the progress of the case in all its details. The boy had been repeatedly exhibited to, and examined by, the class and by medical visitors to the hospital, as affording a typical example of the murmur distinctive of mitral stenosis. On several occasions, especially during the existence of temporary congestion of the lungs, the second sound of the heart was reduplicated, but only within a small space intermediate between, and equi-distant from the orifices of the aorta and pulmonary artery, whilst over either orifice, and externally to it, the sound was single, thus showing that reduplication of the second sound is due to a synchronism in the closure of the two sets of sigmoid valves. A bellowing murmur of systolic rhythm, loudest at lower sternum, and transmitted upwards in the line of the aorta for about two inches was likewise *occasionally* present, and for the last few months an apex-systolic murmur was superadded, but during the last fortnight of life, inaudible for brief periods. The pulse was regular throughout, save during an attack of angina, when it intermitted and became excessively feeble, it ranged between 60 and 108 in the minute. The point of apex-pulsation was gradually displaced outwards, and at the time of death was more than half-an-inch to the left of the nipple-line. The patient was about to leave hospital to resume his duties, when he contracted small-pox ; the eruption was discrete, and the fever mild, the boy having been successfully vaccinated in childhood. On the sixth day of the eruption, he complained of great oppression and dyspnœa, the lungs were partially congested, and the heart pulsated tumultuously, the extremities became cold and congested, and he died suddenly on the morning of the 15th (11th day of eruption), after getting into bed off the night-chair. *Autopsy*—The lungs were found voluminous and slightly attached to the chest superiorly. There was evidence of great pericarditis confined to the right auricle, but no liquid effusion, heart expanded and bifia at apex, the greater part of which was formed by the right ventricle, and weighed 18¼ ounces. Both right chambers were dilated and thickened, and filled with decolourisation, left auricle greatly enlarged and hypertrophied, whilst the left ventricle was slightly thickened, but otherwise normal. The valves and orifices were all in a healthy condition, with exception of the mitral, which was slit-shaped, large enough to admit the tip of the index finger, and bounded by the agglutinated segments of the valve which were smooth and thickened. Irrespectively of the diagnostic value of presystolic murmur which this case illustrates, it is otherwise of interest, as showing the true cause of reduplicated second sound, and as affording an example of death by cardiac thrombosis of slow and gradual development. How far the variolous poison was contributory to this process, if at all, is matter for speculation.

FRACTURE OF THE SPINE.

THROUGH the kindness of Mr. Colles, I have the privilege of laying before the Society an example of fracture of the spine, which presents some features of *interest;* we have here the cervical vertebra of a man about forty years of age, who fell from a height of about sixteen or seventeen feet. He appears to have struck the ground directly on the vertex, that being the only part on which any mark of contusion could be observed. He was taken up in a state of collapse, and it may be remarked that the collapse was more characterised by failure of circulation than of innervation, as he very quickly recovered consciousness, and in a few moments after the fall he gave a very connected and detailed account of how it occurred. He was seen by Mr. Abram Colles, resident surgeon of Steeven's Hospital, who had him at once removed to that institution. He presented the following conditions :—From a line a little above the level of the nipple, there was complete loss of muscular action, both reflex and voluntary ; irritation of the sole of the foot caused a slight flickering movement of the great toe ; but this appeared to be due rather to direct excitation, than to any reflex movement ; there was loss of sensation and marked priapism ; the skin was clammy ; pulse below 40 ; the respiration was carried on by the diaphragm alone. He was perfectly rational, and had power of swallowing ; his head was bent back as in opisthotonos. He passed a restless night, and vomited some dark matter. On the following day, the pulse had risen to seventy ; there was retention of urine, and he presented remarkable hyperæsthesia at the line of junction, between the healthy and the paralyzed portion of the body. He survived the injury forty-eight hours, and died of asthenia.

On making a *post-mortem* examination, a mark of contusion was found on the vertex. On dissecting down to the cervical spine, and passing the finger to the atlas, it was felt to be completely comminuted ; the whole cervical spine was carefully removed by Mr. Colles. One fracture traversed the anterior arch. A second, the posterior arch, which was severed into three pieces ; the transverse process of the right side was broken off. It is a remarkable fact that the odontoid process was not broken. There was also laceration of the intervertebral substance between the fifth and sixth cervical vertebra, the sixth was displaced backwards, with fracture of its laminæ causing distinct compression of the cord. The symptoms were all referrible to this displacement. The extensive injury to the atlas not being indicated by any special conditions; it is further remarkable that this bone should be so crushed between the opposing forces, and that there should be so little shock communicated to the brain, as if it were completely expended by *contre coup.*

The Medical Press and Circular.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, JANUARY 3, 1872.

VOLUME LXVI.

WE commence this week the issue of copies as specimens to the profession. The large amount of practical matter contained in our past sixty-five volumes—the thoroughly independent tone of the MEDICAL PRESS—the fact that it is year by year growing in favour, and the knowledge that it is the only weekly Medical Journal that permits absolutely free expressions of opinion, by those members of the profession who differ on certain questions from the literary staff, inspire us with confidence for the future.

We this week commence a series of communications by W. H. Lee, of St. George's Hospital, and another by Dr. Mapother, of Dublin.

We have in type a clinical lecture on "Chorea," by Dr. Handfield Jones, the first of some papers on "Cataract," by Mr. George Critchett, a paper on "Syphilitic Disease of the Throat, Mouth, and Nose," by Dr. Prosser James, and "Remarks on the Treatment of Asthma," by Dr. Thorowgood. We may also announce papers on "Dysmenorrhœa," by Dr. Head, of the London Hospital, and many other contributions of great practical value. Prof. Erasmus Wilson's lectures at the Royal College of Surgeons, will appear *in extenso* in the MEDICAL PRESS.

1871.

THE expiring year reminds us of the death-roll of our profession ; great and enduring names have, during the past twelve months, been recorded in our "Obituary," and a much larger number of our brethren have died who had worthily filled their places in that sphere in which it had pleased God to place them. They have all left many who miss them, and we may all reflect a moment with advantage on the uncertainty of life. We honour all, but cannot reprint the long list, nor do we know their worth. We may therefore justly follow the custom of many years, and mention only a few whose names will be familiar to the majority of our readers, and who have passed from among us since this time last year :—

Sir John Fife, Dr. Mayo, Mr. Solly, Dr. Symonds, Dr. T. Evanson, Count Wollowicz, Dr. Keith, Mr. Langston Parker, Dr. Salter, Dr. Tanner, and many others known to us are no more. Abroad also the losses are as heavy. Niemeyer was, through translations known in this country, almost as well as in Germany, the mention of which reminds us of the many who fell victims to that horrible war. On both sides our brethren perished in endeavouring to mitigate by their skill, some of the horrors that civilised nations inflict on each other.

◆

SCOTLAND.

EDINBURGH.

We regret to record the death of Charles Sidey, Esq., surgeon, which took place on Thursday last. Mr. Sidey, who was universally respected, was in possession of an extensive practice, and was distinguished for his practical knowledge of the diseases of women and children. He had attained the age of seventy-five years.

ABERDEEN.

Drs. Inglis and Rodger have been elected Medical Officers to the Aberdeen Dispensary.

◆

Notes on Current Topics.

The Etiological Influence of the Use of Tobacco in Producing Diseases of the Nerve Centres.

According to a statistical note inserted in the *Bulletin de L'Association Francaise, contre l'abus du tabac,* of fifty-nine affections of the nervous system observed by M. Famisier from 1860 to 1869, forty-one of the cases occurred in smokers. The following table will indicate respectively the abuse, the simple use of the article, and the effects of abstinence in smoking :—

	Abuse.	Simple Use.	Abstinence.	Total.
Hemiplegia . . .	9	2	4	15
Softening of the brain .	—	1	3	4
Paraplegia . . .	5	3	10	18
Locomotor ataxia . .	14	5	1	20
Trembling . . .	1	—	0	1
Paralysis agitans . .	1	—	—	1

M. Famisier does not conclude that in all the fifty-nine cases the disease has been produced by smoking, but he believes that only to this cause may be attributed the great number of cases of hemiplegia and locomotor ataxia observed.

By watching some patients M. Famisier observed the aggravation of the symptoms whenever the individual indulged in the habit of smoking, as well as an amelioration or diminution in the gravity of the symptoms under abstinence from smoking. His conviction on this point is absolutely firm, and of long standing, and the *Bull. Gen. Therap.* says, "We completely agree with his statements."

The Brown Institution for the Study of Animal Pathology.

So long since as 1852 the late Mr. T. Brown, of Roseyhill park, Dublin, in his will bequeathed to the University of London and their successors a certain amount of stock in the Three per Cent. Consolidated Bank Annuities, and likewise the residue of his personal property, for the purpose of "founding, establishing, and upholding an institution for investigating, studying, and without charge beyond immediate expenses, endeavouring to cure maladies, distempers, and injuries any quadrupeds or birds useful to man may be found subject to." In the event of the University of London not being able or competent to utilise the fund—which has now accumulated to the sum of £22,000 in Consols, within the space of nineteen years—the same was to go to the University of Dublin for the foundation of Professorships in certain languages. After considerable opposition and quibbling, legal and otherwise between the two Universities, the former has succeeded in establishing within only a few days of the time specified by the testator, "The Brown Animal Sanatory Institution." The buildings, which are situated at Wandsworth, consist of three blocks, covering about an acre and a-half of ground. The first block is for the reception of animals under observation and treatment. The second is the chemical laboratory for scientific experiments and research. The third contains the rooms of the resident officers. Dr. Sanderson, who is the superintendent professor, is to deliver five free public lectures during each year. The promotion of the science of comparative pathology by the examination of dead animals, will be the chief aim of the institution; and the cattle plague, the foot and mouth disease, and other maladies to which quadrupeds are particularly liable, will receive that amount of attention which it is hoped will throw valuable light upon these obscure diseases.

The Royal Physicians.

The illness of the Prince of Wales has brought into prominence a point upon which we have often insisted, viz., The value of the services rendered by medical men not only to individuals but also to the State. The most exalted personage is at times indebted to the "Art of Healing," and then our services are often appreciated, but the whole community is constantly receiving from the mass of the Profession similar services to those lately rendered to the Royal Family. Moreover, preventive medicine is perhaps even more valuable, and we all, without exception of profit or reward, silently carry on a work for which humanity must long remain indebted to us. Seldom are the benefits we confer thought about, still more seldom are they acknowledged. It is then with pleasure that we observe that the sad occasion of the Prince's illness has been made the text by many of our contemporaries upon which to utter a simple homily expressive of gratitude to our Profession. We know it is but seldom that in the rush of other matters the neglect shown to medical men by the Government and the people finds expression. Society is careless of its greatest benefactors. Patients too often think that the fee sufficiently rewards the doctor, and sometimes the fee is but grudgingly given, and not unfrequently it is forgotten, or withheld. We appreciate therefore the good feeling that has been exhibited by the general press, and which *The Globe* has very felicitously expressed in an article concluding as follows:—

> "Such thoughts should remind us, generally, of the debt of gratitude that we owe to the members of the noble profession of medicine. That scene of sorrow and anxiety at Sandringham will not fail to be enacted, sooner or later, in our own homes. For some valued life we shall all of us—and, indeed, to most of us it is already but too familiar—have to hang with thrilling anxiety upon the physician's verdict of life or death. Surely, the Healing Art is worthy of all honour, and the men who devote themseves to it deserving of our highest consideration and respect. Look at the opportunities for doing good that daily occur to the Medical man, and in most of these men's lives to do good and kind acts comes as naturally as the air they breathe. Look also at their hard-working lives. No rest at night, no quiet home pleasures, no friendly meetings, can they be assured of even for one half hour. To other professions come repose and relief as time wears on, but to the valued opinion of a skilled physician there is a ceaseless appeal which ends only with his life. Then, again, how discreet, how self-restrained must he be in society, when subjects are discussed about which he perhaps knows the truth, revealed to him in his intimate intercourse with our families and homes. Who ever hears of a betrayal of confidence under these circumstances? And yet we know what a great temptation to most of us it is to appear wiser than our neighbours. All honour to the men who devote themselves so cheerfully to their trying duties. Let our praise and our rewards be given to them without stint, and with a readiness equal to their devotion to our service."

Deaths in the Profession during 1871.

In looking over the "Obituary" as it has appeared from time to time during the past year, we are struck with the number of men of great eminence who are now lost to the profession, of which they had done so much to ennoble. Many, however, had passed the allotted three score years, and among whom we may mention, the following veterans whose ages vary from 75 to 96—namely, Sir John Fife, F.R.C.S. Eng., aged 78; Thomas Mayo, M.D., F.R.S., late President of the Royal College of Physicians, London, 81; Thomas Waterfield, M.D., Cantab., F.R.C.P. London, 81; James Henderson, M.D. Edinburgh, inspector-general of army hospitals, 84; Samuel Barton, J.P., F.R.C.S. England, 82; Robert Dann, M.D. Glasgow, senior member of the Royal College of Physicians, London, and deputy inspector-general, 87; James Watson, M.D, Glasgow, late President of the Faculty of Physicians and Surgeons, Glasgow, 84; Alexander Anderson, F.R.C.S. England, 78; Thomas Mostyn, M.D. Edinburgh, deputy inspector-general and honorary surgeon to the Queen, 82; Henry Anderton, F.R.C.S., England, 81; Christopher Hunter, M.D., St. Andrews, 91; George Curshaw, M.D. Paris, F.R.C.P. London, government inspector of the provincial anatomical schools, 77; Richard Filkin, M.D. Glasgow, army staff, 96; Cornelius Butler, F.R.C.S. England, 82; John Dempster, M.D. Edinburgh, inspector-general of army hospitals, 78; John H. Fuge, R.N. senior fellow of the Royal College of Surgeons of England, 91; Robert Dundas, M.D., 78; Philip C. Delagarde, F.R.C.S. Eng., 75; Sir Jas. Murray, M.D. Dub., inspector of anatomy for Ireland, 84; John M. Pigott, M.D. Edinburgh, 86; William Austin, M.D. Glasgow, inspector-general of army hospitals, 83; and Patrick Miller, M.D., F.R.S. Edinburgh, consulting physician to the Devon and Exeter Hospital, 90.

Catheter removed from a Female Bladder.

Dr. W. T. Briggs (*Nashville Journal of Medicine and Surgery*), reports a case of escape of catheter into the female bladder during its use for the relief of retention of urine. It was removed by the dilatation of the urethra with a sponge-tent, and the employment of dressing forceps.

Dr. Briggs, in 1864, removed a catheter from the bladder, two weeks after its entrance, by dilatation of the urethra with the bougie and forceps. Dr. Briggs remarks in conclusion, that in the *Medical Facts and Observations*, published in London in 1791, by William Ford, is possibly case on record.

The London Hospital.

This great institution than, which none is doing a more important work, has just received the magnificent sum of £10,000 from an anonymous donor. This generosity is very timely for the great East-end hospital was much in want of funds. The gift has been bestowed where it cannot but do great good, for the London Hospital succours the very poorest. It is situated in a district both populous and poor and the funds at its disposal are never enough to meet all the demands upon it. An immense hospital like this, with one of the most practical schools of medicine in closest alliance, is doing a great work for both the present and the future. It depends on voluntary contributions, and this munificent donation shows that there are among us the wealthy and the generous. We do but give expression to public sentiment when we say the donor may be assured that the thanks of the community have been earned by his goodness, and that the blessings of the poor will always be showered upon him.

More about Chloral.

Robert F. Fairthorne (*American Journal of Pharmacy*) gives some of the physical characteristics of hydrate of chloral and its behaviour when brought in contact with other substances. Its aqueous solution produces a dense precipitate when mixed with solution of subacetate of lead.

The hydrate is readily dissolved by alcohol, ether, oil of turpentine, benzole, bisulphide of carbon, and the fixed oils. The solution in the last-named article might prove of value to the physician as a topical application, perhaps available in neuralgia or gouty affections.

When equal parts of camphor (in small pieces) and hydrate of chloral in crystals are shaken together in a vial, and allowed to stand, they become fluid, forming a clear solution. This might also be of use as an external remedy.

When hydrate of chloral and sulphuric acid are mixed, a great reduction of temperature takes place. Both pure chloral and its aqueous solution dissolve morphia freely. Quinia is soluble, to a considerable extent, in a strong solution of the hydrate, six grains readily dissolving in one-and-a-half fluid drachms.

Cinchonia, strychnia, veratria, aconitia, are also soluble in the same menstruum.

When chloral and glycerine are mixed a crystalline substance is formed in a few hours. Chloral is a good solvent for camphor or for crystallised carbolic acid, which it deprives of odour to a great extent, and renders it quite soluble in water.

If caustic soda is added to the mixture of chromic acid and chloral, a bright green colour is produced. With solution of potassa in considerable quantity, a blue colour occurs.

When alcohol is mixed with solution of bichromate of potassa and nitric acid, and heated, after caustic soda is added in excess, a green colour is produced which quickly changes to brown.

Mr. Fairthorne has placed these reactions together so as to compare them with one another, thinking that they might possibly lead to the discovery of a test for chloral.

The Contagious Diseases Act.

Last week we gave space to a memorial which has been extensively signed by members of the profession for a continuance of these Acts. A correspondent has forwarded the accompanying memorial against the Acts, which is being signed and addressed to certain members of Parliament. In conformity with our usual practice of giving publicity to both sides of questions interesting to the profession we are pleased to append the following :—

To M.P.,

Sir,—We, the undersigned electors, believe that the Contagious Diseases Acts sanction vice by regulating it, and encourage vice by trying to make it more safe ; that they also imperil the liberty of the subject by trespassing upon the rights of individuals over their persons (and by employing spy-police), and that periodical examinations harden women in vice by disregarding common feeling and a sense of decency, we trust, therefore, you will in Parliament exert yourself to obtain their repeal.

We are, with respect,
Yours,

(Here follow the signatures)

Hæmostatic Properties of Alnus Incana.

Thomas R. Dupuis, M.D., Prof. Botany in Royal College of Physicians and Surgeons, Kingston (*Canada Lancet*), recommends the Alnus Incana (*Tag alder*), so common in the States and Canada, as an excellent hæmostatic. He has prescribed the bark both externally and internally, and has never observed any ill effects follow its use, except occasionally nausea and vomiting when taken too freely. Four cases are related—three of wounds and one of serious epistaxis—which were successfully treated with this remedy. He has also prescribed it in hæmoptysis and in menorrhagia with benefit; it is also well adapted to any internal or external passive hæmorrhages in which astringents are generally esteemed beneficial.

In closing his article, Dr. Dupuis solicits for the decoction of the bark of *Tag alder* a trial from all those who may be interested in the development of the medical remedies of our own country.

Sir James Paget, Bart., F.R.S., D.C.L., and Sir William Fergusson, Bart., F.R.S., have been elected honorary members of the Royal Society of Sciences of Brussels.

A Home for Middle-class Fever Patients.

First-class accommodation for middle-class patients attacked by fever has now been provided by the London Fever Hospital, which was founded in 1802 for the treatment of patients suffering from contagious fever, and which from that time up to the opening of the new Pauper Fever Asylums was the only institution of the kind in the Metropolis. In pursuance of the objects for which it was established, one of the chief of which was to prevent the spread of contagious fever, the hospital has hitherto been under the necessity of opening its doors to paupers, a class that was originally intended to be excluded, and the committee of management are able to assert, that, by the erection of temporary buildings to meet the emergencies of great epidemics, not a single case of contagious fever has, for many years, been refused admission and sent back to act as a new focus of disease.

The arrangements are as follows :—(1.) Patients will be admitted into the general wards on the recommendation of a Governor or annual subscriber of one guinea, or, as heretofore, on payment of two guineas on admission or of one guinea weekly. (2.) For such patients as require isolation and better accommodation than that offered by the general wards, eight large rooms have been prepared and furnished with every requisite for comfort, in which a single patient, or two children of the same family or from the same school, can be received. The payment for one of these rooms, with the attendance of an experienced nurse, and the care of the resident medical officer and physicians, and including food and medicines, has been fixed at three guineas per week.

The committee are assured that, in making provision for private patients, they meet an urgent public requirement, and they are prepared to extend the accommodation should the demand for an extension arise. We are glad to add that the Hospital will, at the same time, continue to render public services of the highest value, by receiving working men and the members of their families, who might otherwise, through an attack of fever, be compelled to take the first step towards pauperism by seeking parish relief.

A Sensible Witness on Insanity.

The *Pacific Medical Journal* is responsible for the following interesting story :—

There is a certain Dr. J. R. Allen, at Memphis, who has touched a sympathetic cord within us by testifying as follows, when called as an expert in a murder trial in which the plea of insanity was set up; "I have been a practising physician for nearly thirty years ; I have had some experience in cases of insanity, having been ten years medical superintendent of the Kentucky Lunatic Asylum, and during that time had over two thousand crazy people under my charge; I have heard the hypothetical case read by Mr. Phelan ; I am here as an expert, and before answering this question I would like to say that the more I have studied the question of insanity the less I understood it, and if you ask me where it begins and where it ends, neither I nor any physician in the world could tell you ; in fact, on occasions like this, lawyers make fools of themselves in trying to make asses of doctors."

Deputy Inspector-General of Hospitals, D. Mackinon, has assumed the duties of Principal Medical Officer at the Curragh Camp.

A Malingerer in Bed Twenty-five Years.

Dr. Terrell describes, in the *Virginia Clinical Record*, a case of malingering in a female residing in Hanover County, Virginia, who lay in bed twenty-five years, "expectorating live worms," and taking but little food. She had as nurses two cousins, who appear to have entered into the spirit of the fraud and assisted her. One of them dying, the patient, if patient she was, fell under different treatment, and soon recovered perfectly, her legs being as useful as ever, after twenty-five years of disuse.

Duration of Life of Physicians.—A Hint to Life Offices.

It seems that doctors' lives are not so bad as they have been reputed: the "Proceedings of the Massachusetts Medical Society" gives a list of members who have died in 1870 and 1871, thus far, 37 in number. The ages of 32 are given, averaging 60½ years, the extremes being 28 and 84.

The Fatality of Single Blessedness.

M. Bertillon has made a communication on this subject to the Brussels Academy of Medicine which has been published in the *Revue Scientifique*. From 25 to 30 years of age the mortality per 1,000 in France amounts to 6·2 in married men; 10·2 in bachelors; and 21·8 in widows. In Brussels the mortality of married women is 9 per 1,000; girls the same, and widows as high as 16·9. In Belgium from 7 per 1,000, amongst married men the number rises to 8·5 in bachelors, and 24·6 in widows. The proportion is the same in Holland. From 8·2 in married men, it rises to 11·7 in bachelors, and 16·9 in widowers, or 12·8 amongst married women, 8·5 in spinsters, and 13·8 in widows.

The result of all the calculations is, that from 25 to 30 years of age the mortality per 1,000 is 4 in married men; 10·4 in bachelors, and 22 in widowers.

This beneficial influence of marriage is manifested at all ages being always more strongly marked in men than in women.

Label for Bitters.

The *American Agriculturist*, speaking of California Wine Bitters and other concoctions advertised in the newspapers of this coast, recommends the following label: Caution: —Keep the bottles, boxes, or packages in a safe place, where no human being can by any possible mistake swallow any of the stuff.

Bromide of Iron.

This remedy is advocated by Dr. N. H. Norris, of Beloit, Wis. (*North-Western Medical and Surgical Journal*), as nearly a specific in involuntary seminal emissions and spermatorrhœa. He gives it three times daily, an hour before or after meals, in doses of three to five grains.

Hypodermic Injection of Nicotine in Tetanus.

In the last number of the *Australian Medical Journal* a case is reported by Dr. E. M. Wuth, in which he successfully employed this method of treatment. The dose administered was half a drachm of a solution of one drop of nicotine to the ounce. The patient experienced local anæsthesia, and the pulse fell to 60, but no second injection was administered.

The next examination of candidates for commissions in the Army Medical Department will take place in London on February 12th.

Deputy Inspector-General of Hospitals, R. J. O'Flaherty, has been appointed Medical Superintendent of Poonah, India.

The friends of Mr. Holmes Coote, Senior Surgeon to St. Bartholomew's Hospital, will be glad to learn that his health is so far improved as to enable him to resume the practice of his profession.

The Registrar-General's return reports the average aggregate mortality in twenty leading cities and towns of the Kingdom for the week ending Saturday to be thirty-two per thousand.

By the death of Professor John Blyth, M.D., Professor of Chemistry, in the Queen's College, the city of Cork has lost one of its most illustrious citizens, and the profession, a distinguished ornament. The distinguished professor has for years been quoted in our text-books on chemistry, as a great authority, and his analytical acumen and judgment have frequently been called into requisition in criminal trials.

Mr. Appleton has just published a pamphlet "On Drainage." The point at issue, he asserts, is not the drainage of the town but the final disposal of the sewage; in other words, having got the sewage well brought down to the lowest point of the town, what is best to be done with it. He then argues in favour of the wet system as against the dry, contending that what is needed is the making of the former as perfect as possible.

Dr. Bathurst Woodman informs us that the subscription list of the "Dyte *versus* the St. Pancras Guardian's Appeal Fund" must shortly be closed, as the case will be heard this month. This question is of great importance to many hundreds of medical men and other public officers; but at present, only about £90 have been received, and, therefore, Dr. Dyte, in the prosecution of his just claims (admitted as such by the Guardians themselves), is liable to lose some hundreds through the shabby pretext of a mere technical objection.

We hope the subscription will at once receive a large addition.

THE PREVENTION OF VENEREAL AND ITS POLITICAL DIFFICULTIES.

(Special Report, prepared expressly for the Medical Press.)

The question of legislative interference with regard to the gigantic evil of the continual propagation of the Venereal Diseases, and the infliction of incalculable ills on innocent persons, has just now received fresh interest from the Report of the Royal Commission upon the administration and operation of the Contagious Diseases' Act, published within the last few days. Witnesses have been examined, and a Blue Book of unusual dimensions has been printed, embodying the evidence on what the Report admits to be "a most painful and delicate question."

In the conduct of the inquiry the presence was allowed of the representatives of those who advocated the necessity for the existence of the Contagious Diseases' Acts and also the representatives of the agitation so actively set in motion to rescind and abolish them. Every fair-play was undoubtedly afforded by this arrangement.

The Report states, "That having taken a large amount of evidence on the subject of Venereal Disease, though the Medical Profession is not agreed upon many points, yet the more important are sufficiently established, and though improved treatment and habits of cleanliness have mitigated the virulence of the disease, yet it is still one of a most formidable description." How fully the Commissioners were impressed by the evidence laid before them may be seen by the following expression of their opinion:—

"We attach great importance to the maintenance of a system, which if it cannot altogether annul, may at least materially mitigate, a pestilence, which is not like other contagions, of occasional occurrence, but one of perennial growth. The firmness of a former Parliament withstood the storm of clamour with which the discovery of vaccination was assailed by the ignorance and prejudice of the day, and relieved posterity from a scourge which was the terror of earlier generations; and we would fain hope that an attempt to stay the progress of a plague scarcely less formidable in its ravages is not to be hastily abandoned." Indeed, such an enunciation could hardly be avoided in the face of the conclusive evidences derived from the statistics of the Army and Navy Departments, where the good effects produced by the application of "such remedy as may be practicable to the great evil," are plainly shown by the tables put in by Dr. Balfour, the Inspector-General of the Army Medical Department. It may be premised that Dr. Balfour, when speaking of syphilis, confines his statement to primary venereal sores. In Devonport and Plymouth, where from the first the system has been most carefully and vigorously administered, the state of syphilitic disease in 1864, before legislation, showed 274 cases out of 2,481 strength; in 1865, before the Act of 1864 had made any impression, the numbers rose to 342; in 1866, when only women informed against or strongly suspected of being affected with contagious disease were brought up for examination, the number fell to 209. In 1867, when the same system obtained, a further reduction from 209 to 185 was recorded. In 1868, under a monthly examination for the latter half of the year, the figures were reduced from 185 to 159. In 1869, when the fortnightly examination was first instituted, the figures increased from 159 to 162, and in the following year were reduced to 85, or nearly one-half. The strength of the garrison was nearly the same throughout these years.

Taking the aggregate of twenty-eight stations of troops in the United Kingdom, at which the average strength amounted to 500 and upwards, the ratio per 1,000 of primary venereal sores in 1865, was 120; in 1867, before the fortnightly examinations had commenced, except for a few months at Chatham, the disease had fallen to 86; it continued to decrease from 86 to 72 and 60, until it fell to 54 in 1870, when the fortnightly examinations were generally established throughout the subjected districts. The returns of gonorrhœa are fluctuating, and the figures are nearly the same for the five principal stations in the year before the Act of 1866, and in the last year of its operation. Dr. Balfour was of opinion that so far as gonorrhœa was concerned, the Acts had been a failure.

Dr. Balfour insisted that very erroneous inferences are liable to be drawn from the amount of disease existing among the small number of men stationed in any one locality, and prepared a table comparing the condition of the total number of soldiers in the protected with that of the total number in the unprotected districts. The result of this table is, that in the first or protected group the number of men per 1,000 admitted into hospital for primary venereal sores has steadily and continuously diminished during the seven years 1864-70; the successive numbers per 1,000 being 120, 90·5, 86·3, 72·1, 60·9, 54·5. In the second, or unprotected group, no such diminution presents itself, the corresponding numbers per 1,000 being 108·6, 99·9, 90·9, 108·0, 106.7, 111·9, 113·3.

A tabular return follows, showing the number of cases of venereal disease contracted by the crews of Her Majesty's ships at home ports from 1856 to 1869 inclusive, with the ratio per 1,000 of force. In the latter half of 1865, the Act of the preceding year was partially in operation at Chatham and Sheerness. Legal difficulties had prevented its being put in force at Portsmouth, and at Devonport and Plymouth nothing had been done beyond a preparatory enumeration of the brothels and public women. In 1865, the cases of syphilis on the home stations were 108·7 per 1,000. In 1866, still under the partial though more extended operation of the Act of 1864, the ratio per 1,000 had fallen to 76·4. Passing on to 1869, when the periodical examination had been nearly completed in the seaports, the ratio was 59·5. The return of cases of gonorrhœa is remarkable. In 1865, they were 34·4 per 1,000; in 1866, they were 25; in 1869, they were 42·4 per 1,000, the highest number attained during the fourteen years to which the return refers. Dr. Armstrong explained that these figures were not to be taken as a fair criterion of the working of periodical examinations, on account of the constant fluctuation of the crews in the receiving ships. But though no definite conclusion can be drawn from statistics subject to so much disturbance, they would seem to show that since the introduction of the system which commenced in 1864 the more serious form of the disease has diminished while the other form has increased.

While it is thus absolutely proved that an incalculable amount of good has been done, and is capable of being done, by the application of the present Act, the violent agitation of enthusiasts and others who hold strong views as to interfering with the construction of society, or with the liberty of the subject, has not been without its influence. The Report thus notices the two-fold arguments which have been advanced by these opponents, who are, no doubt, earnest and well-meaning.

The first one, as to the necessary interference with the liberty of the subject and the implication of well-doers, is thus dealt with:—

"Among the means adopted by some of the opponents of the Acts to bring them into public odium, have been charges of misconduct or gross negligence on the part of the police in putting the law in force against common prostitutes. Cases have been brought forward in publications and speeches at public meetings, not only of cruel insults offered to innocent women, through the agency of the Acts, but of repeated wrongs to the unhappy women who have been or are subjected to them. We have made inquiry into every case in which names and details were given, We have requested the persons who have publicly made these statements to substantiate them. In some instances the persons thus challenged have refused to come forward; in others, the explanations have been hearsay, or more or less frivolous. The result of our inquiries has been to satisfy us that the police are not chargeable with any abuse of their authority, and that they have hitherto discharged a novel and difficult duty with moderation and caution. Even if it had been proved that they had in some instances made mistakes, or exceeded their duty, such errors might have rendered it necessary to make provision for the more careful administration of the Acts, but would have been no valid argument for their repeal. The charges thus rashly made and repeated, have contributed much to excite public indignation against these enactments."

(*To be continued.*)

Foreign Medical Literature.

THE ANCIENTS ON SLEEP.

(From A. Bouchardat's "Labour and its Influence on the Health.")

Translated for the Medical Press by Joseph Coutenceaud.

I borrow from Hippocrates and from Sanctorius the following quotations concerning sleep :—

Here are first some extracts from Hippocrates :—

"Sleep and watching, carried beyond their just limits, both injure the health; successive watching hinder the digestion and produce crude things: but likewise to sleep too much impairs the body, makes the head heavy, and makes one stupid.

"According to the course of nature, we are made to wake at day-time and sleep at night. People who practice the reverse are sooner or later punished for their folly.

"Let us sleep in a large and well-aired room; but let us always be careful of being well covered during the sleep.

"When during his sleep a man has dreams concerning what he does in the day-time, and the subjects of which are natural and proper things, it is a sign that he is well; it is a token that he wants neither evacuation, nor gathering strength, and at present no illness has begun to impair his health.

"But dreams which are adverse to the acts of day-time produce in the human frame more or less grave disorder, according as those dreams wander more or less from the natural and usual acts of the one who performed them. Therefore I advise in such a case to reach the source of the disease and to labour to prevent or cure that disorder. If, for instance, we dream of an evacuation, it is a sign that the body is too full, and must be cleaned either by emetics, abstinence, or exercise. If we dream that we eat with appetite usual foods, it is a token that the body is empty and must have more food. Mournful and frightful dreams announce in the blood a slackening which must be remedied. These rules are by no means despicable; if observed, the result will soon be reached.

"We must always have great regard to what is usually done, on account of the food, the way of dressing, exercise, sleep, the intercourse with women, and the passions of the mind."

Some of Sanctorius' precepts run as follows :—

"We feel that we have surely slept well, when in the morning the sense is neat, the body quick and nimble.

"Too much sleep makes the body cold, heavy, and stupid.

"The perspiration is more hindered when sleeping we throw off our blankets, than when waking we cast off our clothes.

"A drop of good wine makes us sleep and facilitates the perspiration; as soon as we take more than is necessary, it is an obstacle to both."

SYSTEMATIC HANDBOOK OF VOLUMETRIC ANALYSIS.*

The relative merits of gravimetric and volumetric processes are not so easily determined as would appear at first sight, and the advocates of the one class frequently blind themselves to the perfections of the other.

In its application to some analytical process, the volumetric system is unequalled as regards the accuracy and the quickness with which estimations can be performed. The latter forms a powerful recommendation in practice. As a set off against this, it is absolutely necessary in most cases that the chemicals with which the standard solutions are made should be very pure, and that the said solutions should be prepared with the greatest care as regards strength. In fact, volumetric analysis may be viewed simply a system in which the weighing is brought to a minimum by subdividing a weighing into volumetric division; whilst the element to be estimated is never weighed, either directly or in combination—it being the test alone that is weighed.

Mr. Sutton thus familiarly describes the volumetric method :—Suppose it is desirable to know the quantity of pure silver contained in a shilling. The coin is first dissolved in nitric acid, by which means a bluish solution containing silver, copper, and other metals is obtained. It is a known fact that chlorine combines with silver in the presence of other metals to form chloride of silver, which is insoluble in nitric acid. The proportions in which the combination takes place are 35·5 of chlorine to every 108 of silver, consequently if a standard solution of pure chloride of sodium is prepared by dissolving 58·3 grains in so much distilled water as will make up exactly 1,000 grain-measures, every single grain-measure of this solution will, combined with 0·108 grains of pure silver, form chloride of silver, which precipitates to the bottom of the vessel in which the mixture is made. In the process of adding the salt solution to the silver drop by drop, a point is at last reached when the precipitate ceases to form. Here the process must stop. On looking carefully at the graduated vessel from which the standard solution has been used, the operator sees at once the number of grain-measures which have been necessary to produce the complete decomposition. For example, suppose the quantity used was 520 grains, all that is necessary to be done is to multiply 520 by the co-efficient for each grain-measure, viz., 0·108 which shows the amount of pure silver present to be 56·16 grains.

Volumetric processes of analysis are becoming more fashionable every day, and the fact that they have been adopted in the "Pharmacopœia" for most of the methods of estimating the purity or strength of the preparations therein, render this system of special interest and value to the student of medical chemistry.

Mr. Sutton's book is the standard work upon this branch of applied science; indeed, we may say it is the only one. Originally a well constructed book, it has so grown in importance and size that, in the present edition, we must confess that we have an inclination to view it entirely as an *opus novum*. Too much praise can hardly be bestowed on Mr. Sutton for the careful manner in which he has culled the good and reliable processes from those which are not so valuable. What object can an author have in inserting in such a work a multitude of methods of arriving at the same end. Indeed, the whole of the work is got up with an immense amount of painstaking research, and has established Mr. Sutton's success in this direction.

The term "decem" is peculiar to this work, and may as well be explained here. The author uses it to lessen the number of figures used in the grain system, it is written for shortness "dm.," and corresponds to ten fluid grains; this term bears the same proportion to the 10,000 grain measure as the cubic centimetre does to the litre, namely, the one-thousandth part. However, the use of these terms may prove a weakness on practical working with the book. Thus, at page 80, the author gives an analytical process for the estimation of chlorides, and gives the details of the process in abbreviations, such as "grn.," "c.c.," (grains and cubic centimetres), and then refers to Liebig's method as described at §80·2, which should be §78·2, wherein he gives the abbreviates as "dm." and "grn." (decems and grains).

---

* "A Systematic Handbook of Volumetric Analysis." By Francis Sutton, F.C.S. 2nd Edition. London: J. and A. Churchill. 1871.

After giving the ordinary methods of analysis, Part 6 is devoted to the special applications of the volumetric system to complete quantitative analysis, viz ,urine, soils, manures, water and sewage. We cannot conclude without speaking of the elaborate description given of gas analysis, which is excellently illustrated by engravings. This part appropriately brings to a close one of the most valuable works in connection with analysis which has issued from the press for some time.

Correspondence.

THE PRINCE'S ILLNESS—TYPHOID INFLUENZA.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Is not the fever of the Prince of Wales unlike true typhoid fever? Is not it rather that anomalous fever which I have designated "typhoid influenza," and described at page 264 of your Journal? It differs from true typhoid in its uncertain duration, ranging from a few days to six weeks in the comparative coolness of the skin and slowness of the pulse, in the congestion of the lungs, revealing itself too late. There are also many abortive sweats, as in rheumatic fever. Such sweats are rarely critical; in fact, the only crisis is a herpetic eruption about the lips, seldom seen after the first week. If the vesicles continue plump, it is a true crisis; if they wither prematurely, it is imperfect. There is delirium and diarrhœa, as in regular typhoid. I venture to predict that the Prince won't be over this for another ten or twelve days.

I am, Sir, yours faithfully,

FRANCIS M. LUTHER, M.D.

Cappoquin, 14th Dec., 1871.

◆

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Please to kindly accept my warm thanks for last week's copy of your Journal. It contains a highly interesting and most valuable document on the use of alcoholic liquors as a medicine, which will, I hope, be highly appreciated by all of your readers who are temperance men, by many of them who have not yet given any signs that they are willing to throw themselves into our ranks, and help us in our efforts to get rid of this pestiferous drug altogether.

I am warranted in giving it this ugly name, from the fact that these three hundred (or near it) educated and intelligent men, by the epithets they apply to it, exhibit it as one of the worst medicines they permit to enter into their pharmacopœia.

Your editorial commentaries on this document induce me to trouble you with a few lines.

You apprehend that temperately as this paper is prepared, that temperance folk may be apt to find fault with it. I, myself, do not think this is likely to be much the case; they may however *reason* from it; and prove on the testimony of a large number of Medical men, that it may be better to relinquish its use altogether than continue an article in use so certain to produce such an amount of mischief, when physicians offer it to their patients as a cure for disease. When an article, the taste of which is so highly esteemed in the world, once gets a footing among men, it will be used too freely, even though its evil results be clearly pointed out.

I, as an old teetotaller, feel gratified that so many physicians have put their names to a solemn warning on the subject, and I hope their advice will not fail of being duly appreciated by those under whose care they may come, and who warn them, in each of the three paragraphs of this short letter, that this fearful poison, of which so many have become enamoured is, and has ever been, really accompanied by the saddest results; and their condemnation of it, as a poisoner of health, is given in as emphatic terms as our language supplies.

Several years ago there lived, highly esteemed among us, the late Dr. Neligan. I was speaking with him once on this subject, in our Royal Dublin Society House, and I said to him something to the following effect:—Doctor, I have read every article that has come under my notice for years from Medical men on this subject, and in spite of whatever they may have said in talk about it, I never knew one of them to write on the subject who did not recommend such caution in its use as satisfied us—teetotallers—that it would be better for you all to give it up altogether, in view of the mischief to mind and body it is ever doing in the world." His reply was,—"I have, Sir, done so." He then referred me to an article of his in a Medical journal, which I procured and read; and it was written so much in the strain I alluded to, that I took his letter and wrote upon it in one of our papers, describing what this able physician said of it as a diet and a medicine. I sent my said letter to the doctor; he never replied to it, or ever after reasoned with me on the subject.

I will now give you the opinion of a living doctor of very high repute, who told me he thought every Medical man ordering alcohol should visit his patient three times a-day, to witness its results. "Doctor," said I, "is not this a proof its use should be given up, for you could not find physical strength for such work as that?"

But I must not trespass on your space. I rejoice to see the article you have sent me, and I look with no light confidence to a serious change in Medical practice in this regard arising from such writings.

I am now writing on Christmas Day, and I wish you "Many Happy Returns."

May all our Medical friends take a bolder course in regard to this mischievous article.

Faithfully yours, JAMES HAUGHTON.

Christmas Day, 1871.

◆

CARBOLIC ACID IN SMALL-POX A PREVENTITIVE INFLUENCE OF REVACCINATION.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—As small-pox is now very prevalent in Dublin, a few remarks on a remedy that has been useful in my hands may be interesting to some of those engaged in treating it.

Whilst assisting Mr. Wm. Rose, of High Wycombe, Bucks, Medical Officer of the No. 1 District, Wycombe Union, I treated about twenty cases of small-pox, most of which were treated with mixtures containing carb. ammon. The notes of some cases that were treated by carbolic acid I beg to lay before you.

When J. C., æt. 50, came under my care he was suffering from confluent small-pox, about the seventh day of the eruption. He was very weak, and constantly scratching his face. I ordered a linseed-meal poultice to be applied to his face and hands, the room to be darkened, and the window opened. I gave brandy and beef-tea *ad lib.*, and a mixture containing carb. ammon. During the night, being restless, he tore the poultices off his face and hands. The nurse could not keep them on. I gave him the following lotion, to be painted over the surface with a camel's hair brush, and to wet the poultice with it:—

℞ Acidi carbolici, gr. vj.;
Glycerinæ, ʒvj.;
Aquæ tepidiæ, ad ℥vj.
Misce ft. lotio. m. d. n.

which relieved him very much every time it was applied. He had this lotion repeated several times. His convalescence was very protracted, owing to debility arising from secondary fever, for which he got quinine and generous diet. Under this treatment he did well. This patient never was vaccinated. I thought as carbolic acid did so well externally that if given internally, it might produce the same effects in small-pox that chlorine does in scarlatina.

In the beginning of last February I was called to attend a case of "discrete small-pox," occurring in a healthy child eight years old, who had been vaccinated in his infancy and had one slight cicatrix on the left arm. I ordered him a mixture of carb. ammon. and aq. camph. for three days, which did well with him, and milk and beef-tea. It being a mild case I resolved to try carbolic acid internally. Accordingly, I gave the patient the following prescription :—

℞ Acidi carbolici, M vj.;
Glycerinæ, M xlviij.;
Aquæ tepidæ, ad ℥j.
M. ft. mist. sumet, ʒj. b. q. q. hora.

The carbolic acid was dissolved by heat, the child took the medicine without difficulty, and had it repeated several times, and made a rapid recovery. The secondary fever was very slight. There were few spots on the face. A poultice applied to them relieved the itching. He lived about three miles from High Wycombe, on a rising ground, with few houses near.

The next case was a girl, æt. 16, who had been vaccinated in infancy. I treated her in the commencement as I did the preceding case, with the addition of two minims of carbolic acid in one ounce of our ordinary aq. ammon. carb., and some wine and the carbolic acid lotion to be applied tepid to the face.

In the above cases the secretions from the fauces and nose were very slight. She made a rapid recovery. Her mother, æt. 42, took it from her, and had it very mildly. She was treated in the same way, and made a good recovery. The mother and daughter lived three miles from High Wycombe, where the epidemic first made its appearance.

The last case occurred in April of the present year, about two miles from High Wycombe.—F. B,, æt. 52, a stout, healthy man, but an inveterate drinker of beer and gin, went on a visit to a friend who resided in a district of London where small-pox was very prevalent at the time. Four days after his return from London I was called in, and found him suffering from well-marked "cohering small-pox," by which I mean the pustules touching each other's margins. During the four days previous to my seeing him he suffered from the usual premonitory symptoms of the disease. He was vaccinated fifty years ago, and had a distinct cicatrix on the right arm. He never was revaccinated. He had slight secretions from the nose and fauces. I gave him carbolic acid dissolved by heat in two minims of glycerine and water, and increased it up to four minims every four hours. It checked the secretions from the nose and fauces. The patient said it did his throat good, There was little delirium in this case. The bowels were regular all through his illness. He had brandy and beef-tea daily. The secondary fever and eruption disappeared more quickly in this case than in any other similar case that was treated without carbolic acid. The carbolic acid lotion and poultices were used freely in this case.

All the patients suffering from this disease treated by me received milk, beef-tea, *ad lib.* and brandy and wine, as each case required it. In each case the room was darkened, the windows were open, and a small fire lighted to ensure as thorough ventilation as possible. I never knew a single instance of a patient taking cold from having the windows open. Chloride of lime was used freely as a disinfectant, and perfect cleanliness as much as possible observed by the attendants on the patients. The carbolic acid mixture and lotion might be made of such strength as would be agreeable to the patient's palate and feelings. I have found that ʒss. of water will keep in solution ʒviiss. of carbolic acid dissolved first by heat, which is a very convenient form for dispensing it. Pain in the back was not constant in the cases observed by me. Pain in the epigastrium and nausea were constant except in one case, rigors were in every case.

The worst cases were in those parts of the town where the sewers were most defective, and where they discharged themselves into a river that flowed past the town. When there was good air and perfect ventilation, I never lost a case, where the reverse was, the treatment was not so successful. I would suggest in private cases, that a piece of lint or spongiopiline be saturated with the carbolic acid lotion and applied to the itching surface, and over it some gutta percha tissue. Where the cases were completely isolated, and the convalescent patients not allowed to go about their ordinary business, until the recent appearance of the cicatrices had worn off the face, the further spread of the disease seemed to be checked. I have had two cases of small-pox, in which the disease I am of opinion, was contracted from the sight of recent convalescents. Their appearance frightened these persons the moment they saw them, they trembled all over, and felt nausea, and had the disease in a few days. I had another case where the source of infection arose from the odour arising from a case of small-pox. The patient infected by the case, lived about fifteen yards from the source of infection, in a separate house, with several houses intervening, whose inhabitants escaped. The person who took it had been previously vaccinated, he made a good recovery under the carb. ammon. treatment. It was since the occurrence of this case that I have used carbolic acid. I may here bear my testimony to the value of re-vaccination, as it was the only protection that I had from small-pox, and I have been with cases at all hours of the night and day. When I went to High Wycombe, in the early period of the epidemic, I was re-vaccinated by Mr. William Rose in two places, which took very well. Showing that the protective influence of my primary vaccination had entirely worn out. I was vaccinated when an infant, and re-vaccinated when I was twenty-four years of age. While under re-vaccination, I attended to all my various duties, which were very many. The only inconvenience experienced by me from it, being a slight swelling in the axilla, no feelings of malaise. I have re-vaccinated many men, women, and youths, of both sexes, and have never seen an injurious result follow it. I have an acquaintance with a gentleman, who assures me, that he has been re-vaccinated six different times successfullly, and never experienced any unpleasant consequences from it, and that every new comer to the island he comes from, is vaccinated on their arrival there, and in seven years re-vaccinated again, and they had not had a case of small-pox for the last twenty-six years. It may be well to add, that this gentleman resided principally abroad in the West Indies. Hoping these few remarks may lead some persons to try this remedy, who are more fitted to judge of its value than I am.

I am, Sir, yours faithfully,

James Berry Kenny, L.K.Q.C.P.I., L.R.C.S.I.
Medical Officer, New Town Gore Dispensary District.

Killeshandra, December 23rd, 1871.

WHAT TYPHUS FEVER REALLY IS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—I am glad to find that the profession has, at least, one thoroughly free and independent medium, and that we shall thereby be enabled to give free and full scope to our opinions, and not have them rejected, because, forsooth, they may not chime in with all the old notions of our forefathers. Facts and theory are two different things, and though the latter is pleasing, the former are the most substantial.

I trust the illness of the Prince of Wales will, in some degree, assist in establishing and confirming what I long ago considered to be a fact, and that his case will be published with all the symptoms and mode of treatment, in fact, in my opinion, it is of vital importance, not only to the nation at large, but to the whole world. It is said that His Royal Highness had that disease known as "typhus fever." I have long ago totally ignored fever, as a substantive disease, as a disease at all, I distinctly and emphatically deny the existence of fever as a substantive disease. Is it any reason why anything should be a fact, because it has been tacitly admitted to be so for a very long period? The English word "fever" comes from the Latin word "febris" heat, which in professional language, means "heat of skin." Now comes the point: Is this heat of skin a disease or a symptom only? I hold that it is only a symptom and a symptom caused by increased arterial action; friction causes heat, increased arterial action causes the same, lower the pulse from 130 to 60 and I think you will find the heat of the body lowered acccordingly. Is not this a proof in itself that it is only a symptom and not a disease? The very result proves all that I wish to prove, that this peculiar poison acts upon the alimentary canal, causing congestion, inflammation, and finally, a solution of continuity acts upon the mucus and muscular coats of the stomach and bowels, and occasionally the peritoneum and is really, and in fact, gastro-enteritis. It appears that different miasmatic poisons act upon different parts of the body, this upon the stomach and bowels, that upon the cuticle, causing the disease known as "scarlet fever," another, causing "small-pox," and another "measles," and so on. When this disease is allowed gradually to progress from its first shock, the rigors, when active steps are not taken at its commencement, but allowed to progress insidiously and slowly, without any alarming symptoms to denote its treacherous progress, the results from experience might be readily prognosticated. Congestion, inflammation, &c., of the stomach and bowels, congestion seldom occasions abdominal pain and this is where there is much deception, but as it progresses and inflammation sets in we soon find out where the wrong is.

The tongue and the pulse should warn us against any deception. To what do all the symptoms point? Are not the stomach and bowels the most prominent? The headache and wavering of intellect are only symptoms. Every symptom points out to the great injury the poisoned blood is doing to this particular part of the system, and it is only when its virus has been either exhausted or neutralised, a decision can be arrived at, and then much will depend upon the vigour of the constitution. The practice of the present day seems to me to be of a negative kind merely to combat the symptoms as they appear; but I think that when a physician is satisfied that the poison has been received into the system, he should act upon the probable results and take active measures to prevent, if possible, those which would inevitably follow, and which past experience has proved, and which I think I have shown in the two cases in your CIRCULAR of the 22nd ultimo. There are few inflammatory diseases without fever or heat of skin; then, if fever is a distinct disease you will have two to cure. Which will you cure first? The fever, or the other? If the former, say where it is and how you will proceed. I am, Sir,

Yours most obediently,

ALEXANDER LANE, M.D., R.N.

Clun, Salop, December 20th, 1871.

P.S.—What have we to contend against in this disease? Is it the poisoned blood, or the increased arterial action, or what? Have the vessels, the parts really affected, anything to do with it, or do they merely take the blood from and to the heart? What excited the heart to increase its action? When the lungs become congested, what is the fact? That the veins and absorbents cannot take up the blood as quick as it is poured out, hence congestion. By diverting arterial action by blisters. How quickly the croton oil removed the abdominal congestion, and the blisters diverted the arterial action in the case of W. E., as mentioned in your number of the 22nd Nov. last. It might be said, I presume upon this, and only fancy it, or erred in my prognostication, but it was no fancy in the case of the lady, C. E. Had the case of W. E. not been arrested, the result, no doubt, would have been the same as C. E., and perhaps fatal. A. L.

◆

THE CONTROVERSY ON THE CONTAGIOUS DISEASES ACTS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Though in your last number you state you do not preface your leading article with the motto "Audi alteram partem," yet the observations made in the letter of Dr. C. Bell Taylor savoured so much of the "*tête montée* of enthusiasm," that the subject may be briefly reviewed. The strangest differences of opinion are pronounced. But it is remarkable that surgeons, really of experience in the matter, are unanimous, I might say, in maintaining the efficiency of the Contagious Disease Act; and its operation is demonstrated, beyond doubt, to have had a most salutary effect in restraining the extent of venereal, or, rather infecting syphilitic, affections in the Army and Navy. One fact is worth one thousand theories, and the tables furnished by these departments prove incontestibly the diminution of the disease. As to the operation of the Act, it is therefore useless to dispute its utility, by citing statistics or inferences from abroad or elsewhere. *In* 1865, *the percentage of men in the Army affected by venereal was* 120 *per* 1,000; *in* 1870, *it is reduced to* 54 *per* 1,000. Till this statement is proved to be false, it is needless to dispute the efficacy of the Act, and its immense importance not merely to the Army and Navy, but of necessity to the civil population, and, of what seems unaccountably to be overlooked, to a future generation.

On referring to Dr. Taylor's evidence before the Royal Commission, if we judge from some of his statements, we may well hesitate to endorse his opinions on this practical matter.

Question 19,374. He is asked—"Have you ever heard of women of the town being taken up in such a state of rottenness that they could hardly hold together?"

Answer—"No, I should say it is absolute nonsense."

Q.—"Then if medical men of character and reputation have stated that, you still say it is absolute nonsense?"

A.—"Yes. I should not believe it; as a rule, prostitutes are longer lived and healthier than women who are engaged in an honest course of life."

Q.—"You say it is a wholesome occupation?"

A.—"It does not have the effect of shortening their lives, or injuring their health materially."

So preposterous a statement needs no comment. We must only commend it to the good people of Nottingham, to which place Dr. Taylor's experience seems to be confined.

As to the propagation of the disease to innocent wives, the following is Dr. Taylor's theory, when asked—"How will care and prudence protect a virtuous and innocent wife from being diseased by a vicious husband?"

A.—"I do not see how she can avoid it; he *can* avoid it, and he is the person to blame."

Q.—"She is the person to suffer?"

A.—"Yes, the innocent always suffer."

This is a pleasant reflection for wives, and certainly an easy way of disposing of the difficulty. Indeed, the only remedy suggested is the dubious safeguard of the unlimited propagation of gonorrhœa, and soft sores as thus propounded.

Q.—"You have expressed this opinion that gonorrhœa and soft sores, which form the majority of venereal disease, 97 per cent. at least, are nevertheless great checks on incontinence?"

A.—"Yes."

Q. "And consequently valuable safeguards against the more subtle and comparatively dangerous poison of syphilis?"

A.—"Certainly," it is subsequently added; "but I think if you could get rid of gonorrhœa and soft sores without getting rid of syphilis, you would do more harm than good."

Practitioners in this city will readily admit, according to this theory, that there should be very little true syphilis indeed, but the contrary is too well known. Dr. Taylor's description of the vaginal speculum is, that it "is a long and complicated instrument, which takes a long time to clean." Everybody knows that the simple glass, or tubular speculum, is the one in use; how far the above sensational description applies to, it is a matter of opinion.

"I have a right to say that, in my experience as Ophthalmic Surgeon, these symptoms affect the eye—more frequently, almost, than any other organ of the body, and I am in a position to state that they are very easily cured." How many practitioners could subscribe to this extraordinary announcement?

To these specimens of Dr. Taylor's judgment let us now add what he seems so troubled to give publicity to in the *Lancet*, as the "statement to which he still adheres":—

The "woman is placed in a chair, and her feet attached to moveable projections, the chair is then turned *upside down*, and the woman is exposed in the most indelicate manner possible to conceive." In this extraordinarily absurd position, in order to obtain an examination, the surgeon would probably lie on the floor, or else require the pliable neck of an icthyosaurus, to make a speculation.

The evidence of Dr. Sloggitt suggest a much simpler, and certainly less troublesome, method, endorsed by the Report of the Commission as one than which there is not "any better, or, indeed, any other method of detecting venereal disease in the female." As described by the Government Inspector under the Act, where he alludes simply to an "examining *table*, on which the woman sits by direction of the nurse in attendance."

Each of your readers is as capable of attributing its proper value to such over-heated statements, which surely speak for themselves, and exemplify some of the sensational food suited for the Anti-contagionists. We may well apply to all such advocates—the words of our own Swift,—

"Abi viator, imitare si poteris, strenuem,
Pro virile libertate vindicatorem."

As the subjects referred to are merely quotations, on which anyone can satisfy himself, I do not feel called on to add any name but

OBSERVER.

OBITUARY.

PATRICK MILLER, M.D., F.R.S. Edin.

We have to record the death of another veteran of our profession, at the ripe old age of 90. Dr. Miller was in practice at Exeter, in which city he took up his residence so long back as 1807. He was the Senior Fellow of the Royal Society of Edinburgh, and Consulting Physician to the Devon and Exeter Hospital. He was born on the 21st of May, 1782, and was the eldest son of the Rev. Thomas Miller, D.D., Minister of Cumnock, Ayrshire, and the daughter of Dr. Matthew Stewart, D.D., F.R.S.E., the celebrated geometrician and Professor of Mathematics in the University of Edinburgh. He was educated at the High School, Edinburgh, and subsequently at the University of Edinburgh. In 1804 he graduated M.D., and was elected in 1809 one of the physicians of the Devon and Exeter Hospital, an office which he retained for fifty years, resigning it in 1860. In 1818, on the foundation of the Exeter Dispensary, Dr. Miller became one of the physicians; and soon after was elected to the Lunatic Asylum at St. Thomas, an Institution which is now represented by the Wonford House Asylum. This office he retained for forty years. He early gained the esteem of the public, and became, with the late Dr. Blackall, a leading physician of the county. He had a large and capacious mind, and by no means limited his time and activity exclusively to his professional duties. He took his share in the service of the public as a magistrate, as a trustee of the Exeter Charities, and as a member of the committees of the various charitable institutions of the city. He was one of the original promoters of the Devon and Exeter Institution, the Central School, the Savings' Bank, the Penitentiary, the Institution for the Deaf and Dumb, the Infant School, the Institution for the Blind, the Dispensary, the Water Company, the Refuge, &c. Until within the last eight years, when bodily suffering interfered with his activity, he continued in the unceasing discharge of his various duties. The vigour of his mind was complete to the last moments of his existence, and he retained the most accurate and particular memory of things gone by, while taking interest in all the notable events of the present time. His death took place on the 24th December.

DR. HECKFORD.

Dr. Heckford was born at Calcutta on the 24th of April, 1842, his father was Captain Heckford, well known in nautical circles by his works on navigation. He remained in India till he was fifteen, and was a pupil of the principal school and college at Calcutta, where he took the first prize in every class. On coming to England, he was apprenticed to Dr. A. Banks, of Weston House, Stratford, in 1857, and entered at the London Hospital Medical College in 1859, where is career was unusually brilliant. He gained successively both the hospital gold medal for surgery, and also that for medicine, and filled the offices of resident accoucheur, house surgeon, and medical registrar, one after the other, besides acting on several occasions as resident medical officer (house physician). In all these offices he displayed not only the most untiring energy and more than commonly ardent love of his profession. He was also for a short time house surgeon to the Metropolitan Free Hospital. This is not the place to discuss the causes which led his alma mater to prove, as he was wont to say, a dura mater, to the subject of this memoir. Sufficient to say, that he was the idol of his fellow-students, and that when he found himself left out in the cold by the institution which he so loved and adorned, the loss was certainly not on his side only. When cholera broke out in 1866, he threw himself with his accustomed energy into the work of combatting that dire disease, and worked both night and day with his friend and fellow-student, Dr. Bathurst Woodman, in the newly opened Cholera Hospital at Wapping; the noble band of ladies who volunteered to superintend the nursing there, including the sisters of St. Cyprian, from Dorset square, and others, who left their homes to tend the sick and dying, can bear witness to the singleness of heart and the brilliant intelligence displayed by him towards the patients in those cholera wards. In 1866 he returned to India for a short time, presented with a handsome cup by the students of the London Hospital. He soon returned to England in charge of troops; and on January 28th, 1867, married the youngest daughter of the late William Goff, Esq. The East London Hospital for Children, and Dispensary for Women at Ratcliff cross, was founded by Dr. and Mrs. Heckford, on the 28th January, 1868, and opened with ten beds, in a warehouse bought by them for £2,000, the freehold of which they presented to the committee in July, 1870. It rapidly increased to forty beds, and is now about to be further enlarged on a site selected by him. How he worked, how they both worked for the welfare of this hospital has been graphically told by the late Charles Dickens in his paper entitled, "A small Star in the East." Dickens came unsolicited and unexpectedly to the hospital, and glowing as was his description, it was but a faint picture of the reality. It is not too much to say that his labours there, and the consequent anxieties, laid the foundation of the pulmonary disease, which proved fatal on the 14th December, 1871, at Ramsgate. In the intervals, he paid two visits to Italy. On the first occasion, his ardour for work only allowed him to remain one month absent from his work, and again in 1870, after wintering in Naples, he insisted on returning to his post in March, too soon, alas, as it shortly proved. Dr. Heckford was a sound diagnoser and a brilliant operator. Successful cases of lithotomy, amputation of the hip-joint, and elsewhere, resection of joints, and the like, sufficiently attest this. He revived the operation Paracentesis Capitas with gratifying although partial success. His style was facile and forcible; and both Indian and British medical journals contain many cases reported by him. He was also author of "Papers on post-mortem examination of Still-born Children and Young Infants" (L. H. R., vol. I., p. 237), and a "Statistical report of the London Hospital Maternity Department" in the same volume, and on "Circumcision as a Remedial Measure in certain Cases of Epilepsy, Chorea, &c." (Ibid, vol. II., p. 58), and, jointly with Dr. Woodman, of a report on the cholera patients at the Wapping Hospital (Ibid, vol. III., p. 471), and of a paper on a "Malignant Disease of the Vagina in an Infant at Ten Months," Obstetrical Society's "Transactions" (vol. X., p. 224), and "Suggestions for Prevention of Infant Mortality" (Ibid, vol. II., p. 145). Instead of founding a hospital simply for his own profit, he always objected to practising for money, and whenever he took a fee, gave it to his hospital.

Dr. Heckford practised for a few months only at Broad street buildings; and for the last two years of his life, retired occasionally to a little farm near Chigwell, in Essex, taken for the purpose of benefiting Mrs. Heckford, whose health, like her husband's, was undermined by self-denying labours at the Childrens' Hospital. Dr. Heckford was a member of the Obstetrical and Pathological Societies, and of the Beaumont Medical Society, of which he was the life and soul.

Medical News.

The Chicago Medical College escaped the late conflagration, but the Rush Medical College did not. The professors of the latter are giving their course of lectures in one of the hospitals.

The Sanitary Condition of St. George-in-the-West.—D. Aldis, the energetic medical officer of health for the St. George's district, has just issued an able report of his labours to improve the sanitary condition of the district, together with a tabulated statement of the number of deaths from zymotic and other diseases. The number of deaths during the year were 2,049, including 266 in St. George's Hospital. The total mortality shows an increase over 1870 of 212 deaths, chiefly attributable to zymotic diseases. Scarlet fever carried off 137 against 64 of the previous year. Three firms were fined at the instance of Dr. Aldis, for infringement of the Workshops Regulation Act, examples which have had the desired effect upon other large employers of labour, in the better ventilation of their workshops.

Gleanings.

Polygonum Hydropiper.

J. S. Unzicker, M. D., Cincinnati, Ohio, recommends the saturated tincture of Polygonum Hydropiper (water pepper) as an emmenagogue. It was first recommended by the late Prof. John Eberle, in cases of amenorrhœa, in tea-spoonful doses, three or four times daily. It was extensively used for many years by all the leading physicians of Cincinnati, and highly spoken of. This reputation it retained so long as the tincture was made of the right material, and the remedy given in the proper cases. But when it fell into empirical, both medical and pharmaceutical, hands, and was given indiscriminately in all cases, and often made of the wrong material, it had, as a matter of course, to fail in many, and in consequence, like many other good remedies, was laid aside and partly forgotten. Dr. Unzicker believes it is the safest and best remedy in cases where the general health is not impaired, but when the menses are checked by cold, mental emotion, or other like cases, where you wish to bring them on without fear of producing congestion of the head or chest, a sequence to be dreaded.—*Medical Record.*

Statistics of Diseases of the Bone in the Vienna Hospital.

Drs. Alfred Menzel and Herman Perco, in order to determine the frequency of caries in the different bones, and the relation of chronic disease of the bone to tuberculosis and other chronic diseases of the internal organs, have examined the autopsy reports of the General Hospital of Vienna for the last half century, and tabulate their results as follows.

In 52,256 autopsies were found 2,106 cases (4 per cent.) of chronic disease of the bones, viz. 1,996 of caries and 110 of necrosis. These were divided among the different bones as follows :—Skull and bones of the face, necrosis 21, caries, 205 ; vertebræ, caries 702 ; sternum, clavicle and ribs, necrosis 16, caries 184 ; scapula, necrosis 5, caries 4 ; shoulder-joint, caries 28 ; diaphysis of the humerus, necrosis 5, caries 13 ; elbow-joint, caries 93 ; radius, caries 2 ; ulna, caries 4 ; wrist-joint and bones of the hand, caries 41 ; pelvis, necrosis 17, caries 80 ; hip-joint, caries 189 ; femur-diaphysis, necrosis 24, caries 31 ; knee-joint caries, 337 ; tibia-diaphysis, necrosis 20, caries 30 ; fibula-diaphysis, necrosis 2, caries 2 ; ankle-joint and bones of the foot, caries 150. Total, 110 cases of necrosis, 1,996 of caries.

Cases of pure necrosis after osteo-myelitis and acute periostitis were rare. The vertebræ were the bones most frequently affected with caries ; in 185 cases the cervical, in 310 the dorsal, and in 199 the lumbar vertebræ were diseased. In 8 cases the seat of the disease was not given.

In 527 cases the exact vertebræ was stated : the second cervical and the sixth dorsal were the most frequently diseased, then in order, the fifth, eighth and seventh dorsal and first lumbar ; then the third cervical and the third, fourth, ninth and tenth dorsal and the fourth lumbar, &c. Next in frequency to caries of the vertebræ came caries of the knee-joint, and next caries of the skull and of the bones of the head, the 205 cases of the latter gave 100 of caries of the petrous portion of the temporal bone.

Of these cases 1,295 were males, 811 females ; but this does not prove the greater frequency of the disease among men, for the number of males in the hospital is always greater than that of the females.

In 22 per cent. of all these cases there was no chronic disease of the internal organs. In the remaining 78 per cent. such disease was found, showing that the result of all the cases is very important in considering the prognosis of carious processes.

More than a fourth of the cases of caries which were dissected (21·1 per cent.) showed chronic diffuse disease of the abdominal glands ; and of these, caries of the head and trunk was noted in 21·5 per cent. ; of the upper extremities in 26·6 per cent. ; of the lower extremities in 32·8 per cent. From this it appears that the latter predispose to such abdominal diseases ; but it is remarkable that 42·8 per cent. of the shoulder-joint cases also showed such a complication.

Caseous masses, ulcerations, cavities and tubercle were found in 54·2 per cent. of all the cases of caries.

In some cases very perfect caseous masses were found surrounding the carious joints; the combination of miliary tubercle with caries without caseous masses was less frequent than those of caseous masses in combination with caries without true tubercle. This seems to show that caries very seldom leads to tubercular infection, except in combination with caseous masses in other parts of the body, especially in the internal organs ; this combination is apparently the result of the so-called scrofulous diathesis. A direct relation between caries and miliary tuberculosis could not be discovered.

Among the special internal diseases found with caries were hydrocephalus, chronic or subacute, most of the cases occurring with caries of the upper extremities ; purulent meningitis, seldom, however, with caries of other bones than those of the head ; amyloid degenerations, most frequent of the liver, next of the spleen, next of the kidneys. These diseases of the internal organs occurred chiefly with caries of the diaphyses and of the bones of the chest and pelvis, while caseous matter and tubercle were generally found with caries of the joints of the spongy bones.

Studying the diseases of the internal organs according to the locality of the caries, it is seen, for instance, that with caries of the vertebræ no internal disease was found in 24 per cent., caseous masses and tubercle in 56·8 per cent., and chronic diffuse disease in 22·2 per cent.—*Schmidt's Jahrb.*, No. 7, 1871.—*Allg. Med. Central. Zeitung*, No. 73, 1871.

NOTICES TO CORRESPONDENTS.

Several communications and reviews are unavoidably postponed.

Dr. R. E.—Many thanks for your attention. We have received your letter of the 26th. Probably, by this time, you have received what we sent. We shall be glad to receive the article proposed.

Dr. D. S.—The journals have come regularly to hand. We have written you a private letter.

Dr. de Pascale's article shall appear shortly.

The Siamese Twins.—A Correspondent in New York says there is a probability, that in the course of a few days, the much vexed question as to the possible separate existence in health of these abnormal beings, will be likely to receive a forcible solution. One of them is on the point of death, and in the event of this occurring, it is proposed first to separate the head from the trunk; this will, of course, determine whether had they been parted earlier in life, they could have lived a separate existence. The subject is creating considerable excitement in professional circles in America.

"Remarks on Medical Nomenclature." By R. Bingham, M.A. Received, and will appear in our next.

Dr. Carey, Taunton.—Many thanks.

Mr. Wright.—Yes ; in the course of the present month.

L.R.C.P. of Edin.—We have not seen the paragraph to which you refer. Perhaps you can forward us the paper in which it appears.

Dr. Kisch, Liverpool.—The back numbers will be sent you as soon as they can be looked out.

Received :—

A FEW PRACTICAL REMARKS ON THE TREATMENT OF CATARACT.

By George Critchett, F.R.C.S.,
Senior-Surgeon to the Royal London Ophthalmic Hospital, Moorfields.

Although there have been so many contributions made to the literature of this branch of Ophthalmology during the last few years, and although these essays have emanated from such varied sources both British and Continental, yet I think it must be acknowledged that the professional mind is in a somewhat vague and unsettled state as to the most approved methods of operating, and as to the selection of any particular method in any given case. For, although each operator may have settled the question in his own mind and may feel indisposed to submit to any authority but his own, yet it frequently happens that the profession seek to know how the matter stands, and if there be any important innovations on the old established methods and, if so, the grounds of such unsettling of former landmarks.

It may be said that every man who operates for cataract at the present time "does that which seemeth right in his own eyes," and that there is a curious absence of law and authority to regulate our proceedings. This may, to a certain extent, be inevitable, but it is a source of great inconvenience to those who have to teach the subjects, and to those who have to learn, and it is not altogether creditable to science. If the question had been put some few years ago, say for example at the College, as to the methods of operating for cataract, there would have come the glib answer, that soft cataract and congenital cataract must be removed by absorption by means of a needle operation, and that hard cataract must be removed from the field of vision by depression, or couching, or by flap extraction. At the present day such an answer would not meet the views of the modern school. Some forms of congenital cataract are not removed at all, soft cataracts are sometimes removed and not left to the tedious process of absorption, and hard cataracts are removed otherwise than by flap extraction. Thus there is a thorough uprooting of the old-established methods, which it behoves us all to understand and to estimate. It may, therefore, be both interesting and profitable to inquire into the causes of this unsettled state of things, and to endeavour to establish some general principles upon which a more uniform method of proceeding may be founded. If we carefully inquire into the causes that have led to the introduction of various modifications in the method of operating for cataract during the last few years, we shall find that the chief has been a restless and laudable anxiety to reduce the average of failures, and to improve as much as possible not only the average of numbers, but the completeness of the success of the cases operated on. There was a time when the average of failures was more than fifty per cent., this has been gradually reduced to ten per cent., or even rather less in the hands of the best operators. This great change for the better has been produced by improved methods of operating, by increased dexterity on the part of the operator, and by improved methods of after-treatment. Even within my own recollection the averages of failure have been reduced one-half. In the event, therefore, of a case not succeeding, the thoughtful and conscientious oculist must put to himself the question: Why did this case fail? Always granting that the requisite amount of manual dexterity has been exercised, and that the hand has accurately executed that which the mind intended, we must attribute the failure either to the kind of operation selected which may not have been the one best suited to the particular form of cataract or to the particular state of the constitution; or again there remains the alternative which is balm to the conscience of the oculist, that the constitution was in such a depraved condition that no operation however well chosen or however well performed could have succeeded. If, however, the case has failed from suppurative inflammation of the cornea spreading to the other tissues, the question arises, if the true corneal tissue had not been wounded, but if the incision had been made in the white corneo-sclerotic tissue where the wound for an ordinary iridectomy is performed, and where suppuration is so rare, might not this destructive form of inflammation have been avoided; or again, the failure may arise from a secondary form of iritis gradually involving the deeper textures. In this case the local and constitutional conditions that would favour and produce such a result would be totally different from those that induced suppuration. Other sources of failure may be indicated, such as the presence of the lens or of a fragment of the lens within the eye, the occurrence of prolapse of the iris, &c., all of which may be avoided. We are, therefore, driven to the almost Utopian conclusion, that if we could in each case previously ascertain what was the particular type of inflammation to which the constitution was obnoxious, we might select that kind of operation not prone to take on that form, and thus reduce the average of failures to a minimum.

In order clearly to understand the present state of the subject, it will be desirable to glance briefly at the various methods of treating cataract surgically that have successively prevailed, tracing them gradually up to the present time, and bringing each method into court so as far as possible to weigh and set forth their respective merits and demerits.

This can be most conveniently done, and a summary and judicial estimate of merits and demerits most conveniently made, when the entire case is before us, and each method, ancient or modern has been touched upon. We may however remark, in a preliminary way, that every operation has about it the elements of a compromise; some serious objections can be brought against it. The very best may be utterly unsuited to a particular case, or to a particular state of constitution; the very worst may, in some rare instances be the one most likely to obtain success. It would therefore seem to be highly unphilosophical to select any one method to the exclusion of all others. The chief object to be aimed at is success; failure must involve a reproach: a serious loss to the patient, an inevitable painful reflection to the operator. An eminently judicial mind, a rare power of calculating chances, and a keen insight into the specialities of each case are needed before the operation best adapted to the case be decided on.

When we consider how striking is the effect of a successful operation for cataract and how legitimately it has been ranked as one of the greatest triumphs of our art, and one of the greatest boons that science has bestowed upon humanity, it is no wonder if we find that it has enlisted a large share of the mental resources of many of the most distinguished ophthalmic surgeons both British and Continental from the earliest date. The problem that had to be solved when first cataract attracted scientific observation, and that has forced itself more or less upon the attention, and taxed the ingenuity of successive oculists, even up to this hour, is the easiest, and safest, and sometimes the shortest method of removing the opaque lens from its obstructive position within the eye. The history of the earlier efforts in this direction is buried in obscurity. It is probably far more ancient than any published record. The appearance of a cataract would stimulate the inventive faculty of the surgical mind by presenting an obvious obstruction challenging removal by means of some operative proceeding. The readiest plan of disposing of such a solid opaque mass within the eye that would suggest itself to the mind would certainly be to push it down out of the way, to lower it into the soft bed of the vitreous humour, to couch it or put it to bed; thus couching was the expressive word first employed to designate this operation. The effect of this operation, when first performed must have been startling, and well nigh miraculous, with various modifications, and under different names such as depression, reclination, &c., has held its sway until a comparatively recent period, and even after the more scientific method by extraction was initiated much time was needed before it was able to assert its superiority and to supersede displacement, and to this hour there are probably individuals who still perform the ancient operation. Nor is this to be wondered at. Years elapsed before any other plan suggested itself, and even when the first conception of extraction of the cataract dawned upon the mind, it presented so many difficulties and dangers, and required such manual dexterity that couching still retained for a long period a strong hold upon many ophthalmic surgeons. The operation possesses many intrinsic attractions; it is performed with a needle, and leaves no appreciable wound, the effect is very immediate and very complete, it is done with comparative ease, any mistake in the performance will probably be overlooked, and is not very obvious to spectators, the after treatment is mild and brief, the result is quickly obtained and readily available. Thus the difficulty seems to be put away for ever out of sight, the eye looks the same in every way, as if nothing had been done, and vision is for a time at least restored in a certain average of cases. Although the operation presented these numerous advantages, yet an extended experience, the advance of ophthalmic science, and a large average of failures have induced a well grounded belief that this method should be reserved for rare and exceptional cases, if indeed as some contend it be not abandoned altogether. The displacement of a cataract into the posterior chamber gives to it at once many of the elements of a foreign body; it rarely becomes absorbed, and it is liable at any time and from slight causes to further displacement in various directions; thus it may sink down and press upon the retina, or fall forwards upon the ciliary region, or may rise again and obstruct the pupil, and thus various injurious results may be produced upon the eye. Pressure on the retina may gradually destroy its function, or irritation of the ciliary nerves may give rise to glaucomatous symptoms, and set up a deep-seated ophthalmia; and even cases that seem to promise a favourable result may, and often will, gradually fade out without any obvious cause, but probably under the blighting influence of the lens floating in the vitreous chamber, and thus lessening the longevity of the eye. So that when we take this operation into court and let in the light of modern science, we are not surprised that a severe verdict is passed upon it. At the same time it admits of doubt whether we are justified in discarding this operation *in toto*. It is possible that, after carefully weighing the chances, there may seem to be such potent objections to the infliction of any incised wound in the eye, the failure of any form of extraction may seem so probable that, in the interest of the patient we may feel called upon to depress the cataract. Suppose for instance that a carefully and skilfully performed extraction in which each step of the operation went well, has been tried in one eye, and has been followed by destructive inflammation, and supposing that the patient is aged, and the cataract hard and fully formed, and that the constitutional causes which led to the failure exist in at least equal intensity at the time when an operation is contemplated on the second eye, we should probably be giving the patient the best chance of regaining some sight for the few remaining years of his life by depressing the cataract; and I hold it to be both more philosophical and more humane to select an unscientific and faulty operation and succeed, than carry out the last modern idea in the most dexterous manner, and fail to restore sight.

(*To be continued.*)

◆

CLINICAL LECTURE ON CASES OF CHOREA.

By C. Handfield Jones, M.B. Cantab., F.R.S.

Physician to St. Mary's Hospital.

Case I.—J. G., female, æt. 7, admitted Oct. 22nd, 1870. Has never had rheumatism. Had a cut on the head six months ago, which bled and discharged a great deal. Symptoms of chorea first appeared about three weeks ago when her sister was giving her a bath; she could not hold herself still at all, this continued two days later, and got worse since. She can feed herself and walk about, but is unsteady in her movements.

To-day (24th) she was calm and smiling when I came into the ward, did not cry when I came up and inquired about her; but on her sister coming to see her she began to cry passionately. She is not at all anæmic. Heart sounds normal; weight, 38 lbs.; urine, 20 oz. in 24 hours, sp. gr. 1019.

Potass. bromidi. gr. v.;
Quin. disulph. gr. j.;
Acid muriat-dil., ♏ ij.;
Spt. æth. chlor. ♏ vj.;
Aq. ℥ss. *quater die.*

28th.—Runs about the ward freely, but is unsteady if she stands still. Sounds of bronchial catarrh in both backs.

Nov. 2nd.—Not improving decidedly.

Liq. ferri Muriat. ♏ x.;
Calcis. hypophosph., gr. v.;
Spt. æth. chlor. ♏ x.;
Aq. ℥ss. *ter die.*

9th.—Same; eats well as before.

Chlora, gr. vj.;
Aq. ℥ss. *ter die.*

12th.—Can walk steadily along a plank six inches wide; seems almost quite well. Heart's sounds are healthy.

Ferri. carb. saccht., gr. x. *ter die.*

Went out soon after. The duration of the disease in this case, which was a mild one, was about six weeks, three of which had passed before she came under care. Emotional hyper-excitability was well marked. There was no rheumatism or endocarditis.

Case II.—A. S., female, æt. 13, admitted March 3rd, 1871. Has suffered much anxiety, her father being a drunkard; she has had no rheumatic or brain disease. She looks fairly healthy. Had scarlet fever when very young; was taken ill fourteen days ago, her hands were first affected, she dropped anything she tried to hold, afterwards, her walking movements became unsteady. She is now very restless, cannot feed herself or carry a cup of liquid to her lips, chews pretty well; her legs are especially unquiet, are jerked about spasmodically. She can grasp pretty well, equally with both hands. Heart's sounds normal; pulse 88, regular; temperature, 98·6; respiration, 22; urine thick with lithates, acid, sp. gr. 1032.

Potass. bromid, gr. x.;
Ferri. bromidi., gr. v.;
Aq. ℥j., *ter die.*;
Ord. d. porter oss;
Port j. oz—pudding.

March 8th.—Her weight, 64 lbs.; urine of 5th and 6th (24 hours), 16 oz., sp. gr. 1032, thick with lithates; total urea, 300 grains, total phosphoric acid, 29·84 grains, total uric acid, 2·5 grains.

10th.—Lies pretty quiet while left alone, but has even more jactitations than before when she is fed, or washed, or moved in any way. Is fretting to get home.

Succi. conii., ʒij.;
Aq. ʒvj., *quater die.*

15th.—Is a good deal quieter, but can't feed herself yet.

21st.—Is getting on nicely, can sit up in bed and feed herself well, good appetite.

22nd.—Was very pale early this morning and seemed quite ill in the night, is crying and fretting, eats heartily, tongue clean, pulse, 90, weak; temperature, 97·9.

Ferri. et. quinæ. citras. gr. v.;
Tr nucis. vom, ♏. v.;
Aq. ℥ss. *ter die.*

25th.—Is getting quite well.

29th.—Doing quite well. Urine, 26 oz., sp. gr. 1021, palish, nearly clear; total urea, 280 grains, total phosphoric acid 24·7 grains, the analysis for uric acid gave only a blue powder as a precipitate. Went out on 31st.

Duration of illness.—Fourteen days before admission, twenty-eight days after—forty-two days. No rheumatism or endocarditis; no elevation of temperature; no improvement from bromides in seven days, but speedy amelioration from conium, and further improvement from ferri. et quin. citras. Excretion of urea and phosphoric acid, somewhat greater during disorder than during convalescence. Uric acid, absent during latter period and uroglaucin present.

Case III.—Ann O'K, female, æt. 13, admitted April 28th, 1871. She looks very pale, poorly, and feeble; had scarlet fever six years ago, discharge from ears ever since. Is slightly deaf, most on the right side; never had rheumatism; was taken ill three weeks ago with tremor of right hand, none of leg. The hand is shaking in tremor most of the day, it becomes now and then quiet for five minutes, and then she has pain at right shoulder and right lower side and epigastrium. About twice a day she gets attacks which are said to be fits, in which her limbs are rigid, her eyes turn outwards, her face is rather flushed, and she is unconscious. She had one as I sat by the side of her bed, and during it I could not get her to answer questions. In the fits sometimes both hands work, sometimes only the right. She can't keep the hand which trembles still, she can hold things with it, but has no feeling in it. No worms ever seen. Parents and six children, some younger, some older, are exempt from fits. Pulse 75, weak; appetite very good; feet do not swell; no injury to head known of, heart's sounds normal. Urine (29th) not albuminous, sp. gr. 1020.

Succi. conii. ʒj.;
Aq. ʒiij. *ter die.*

May 12th.—Is better, hand quite steady to-day, she gives it me quite steadily. No attacks yesterday or today.

6th.—No fits, walks about quite well and steady, hand quite steady; she can stretch out her arm well. Omit the conium. Olei. morrh. ʒij. *semel die.*

10th.—Had three attacks yesterday evening, having been quite well and about all day; the sister says they seemed to be of hysterical character. Hand quite steady.

13th.—Had another quasi-hysterical attack last evening, but much less severe.

Ptc. oleo. vini. ferri. ʒij. *bis die.*

17th.—Gets on very well, no more attacks, seems quite well in every way.

20th.—Gone out.

Duration of illness.—Three weeks before admission, three weeks or less after—five or six weeks. No rheumatism, or valvular mischief; speedy arrest of tremor (apparently) by conium; cessation of attacks of epileptoid disorder under restorative measures. The case was properly rather one of choreic tremor, than chorea proper, and was complicated with hysterico-epileptiform seizures. The alternation of the motor with sensory disorder (pain) was very noteworthy.

Case IV.—E. W., female, æt. 18, admitted April 28th 1871. She came up to London from Wiltshire to take a place as general servant on the 25th. On 17th she found she could not use her right fingers properly, just before that she got into a great perspiration in chapel when she was feeling very weak; has not felt strong for six months. Seems to have been over-worked in her last situation, which she left three weeks ago. Her right limbs are weak and she can't use them properly; can't wash her hands; almost falls down sometimes. She has evident chorea of the right limbs. Last few days cannot speak so plain as usual; has pain and giddiness in head at times. As she lies in bed, is continually fidgetting and moving about. Has never had rheumatism or any other illness till her present. Catamenia regular; bowels open; tongue rather coated; heart's sounds normal; is in good flesh and colour. Temperature, 98·6. Can only eat a few mouthfuls at a time. Pulse 84, of fair force; expression of face, wilful and tempery.

Succi. conii. ʒj.;
Aq. ℥ss. *ter die* ord. diet.

May 3rd.—Is very troublesome and complaining; complains much of nausea, and drinks warm water to make herself puke; has frontal headache, and sobs and cries;

right hand is steady now, drags her right foot a little in walking. Half ord. diet, pudding.

Assafœtidæ, gr. x., in pil. ij. 3^{ties}h.;
Omitt. mistr. conii.

6th.—Is still in a rather strange state, but seems better on the whole. I propose to her, by way of encouragement, a visit, when she is better, to the Zoological Gardens.

8th.—Temperature 104° ; pulse, about 90 ; throat sore since yesterday evening ; face red, no rash ; throat much inflamed ; tongue moist, coated ; much tremor of limbs.

Tr. belldadon. ♏ 20 ;
Aq. ℥ss. 2 dishor.

Throat to be steamed.

9th.—Seems very restless ; is very strange, sister thinks her not right in her head ; throat much swelled on the right side ; swallows pretty well ; had fish to-day. Temperature 101·8° ; pulse, 105.

Pulv. ipecac. gr. 20 stat.

10th.—Throat decidedly better ; belladonna left off after seven p.m. last night ; tonsils less swollen, moist. Temperature, 99·7°. Has been extremely troublesome, full of mischievous pranks, jumping out of bed, &c. ; was injected subcutaneously with morphia last evening, which quieted her somewhat. Threatened with actual cautery and shower bath.

11th.—Same nearly.

Succi. conii., ʒij. ;
Aq, ℥j. *ter die.*

13th.—Is decidedly better and quieter.

15th.—Much better, is quite well behaved now, right hand much steadier, but she does not feed herself with it ; throat nearly well ; there is an evident ulcer at the attached margin of the soft palate. Pulse 70, weak and soft.

17th.—Doing well, hand much steadier, is now a very good girl indeed, the sister reports.

20th.—Doing well, but complains of pain in left hand, cannot use it so well as right now.

24th.—Complains of headache, and is fidgety with her hand while I am speaking to her, but carries a bowl of water, a tray, or anything almost at other times ; is rational and well-behaved.

Zinci. valerianatis, gr. ij. ;
Extr. cannabis ind., gr. ½ *ter die.*

June 3rd.—Seems almost well, very little complaint of head.

6th.—Goes out.

The chief point here is the curious mingling of motor disorder and mental. The attack of quinsy, attended as it was with notable rise of temperature, was quite accidental. The headache, on the contrary, belonged, I believe, to the same derangement of innervation as the chorea and the quasi-mania. The latter may have been aggravated by the belladonna, but as the derangment existed before it was given, and persisted two days or more after its omission, much importance cannot be assigned to this cause. There was no rheumatism or endocarditis.

CASE V.—W. B., æt. 10, admitted May 3rd, 1871. His mother says that he has been always a nervous excitable child, but has never had any serious illness, has never had rheumatism. For some weeks he has been drooping and losing strength, and during the last three, he has been showing symptoms of incipient chorea. He can walk and feed himself, and make some imperfect attempts at writing his name. There is, however, much unsteadiness and jactitation of arms ; less of his legs ; tongue clean, red ; bowels open from medicine. No worms seen, but has suffered irritation about anus. First sound prolonged, and murmurish at base and apex, scarcely a complete murmur. Pulse weak, 96 about.

Diet simple, fishand pudding ; succus conii was ordered in doses increased from ʒss. up to ʒij. *quater die*, associated during the last week with ol. morrh. ʒij. *in dies.* By May 17th, there was no decided improvement. The urine was clear, of sp. gr. 1030 ; syrup. ferri. phos. ʒj. *ter die*, now replaced the conium, but as on 19th, he appeared worse, this was exchanged for chloral, gr. viij. *ter die.* His urine the following day deposited a large quantity of crystalline uric acid (white).

On 22nd his state was much the same, the sister reported that he seemed to have a sort of fit in the night, from 1 to 2 a.m., he snorted, cried, and tossed about ; was apparently awake.

Ordered Potass. bromid, gr. xv. ;
Mist. quin., ℥j. *ter die.*
Port, 2 oz.

24th.—Rather better ; shower bath.

27th.—No better ; great involuntary struggling during shower bath.

Santonine, gr. ij. o. m. ;
Ol. ricini. aur. seqt.

29th.—Bowels well moved, no worms found in stools.

Argenti. nitratis, gr. 1-6th ;
Extr. cannab. indic., gr. 1-6th, in pil *ter die.*

On 31st, I learnt that he had had pain in and about the left ear for a week, and that purulent discharge had occurred the last two days, since which the pain had been less. The mastoid region was very tender to pressure. Chorea unchanged.

Omit. pil. himd. ij.;
Post. aur. sinistr. ;
Lotion of liq. plumbi. diacet ʒj. ad. aq. ℥vi.
to be injected.

June 2nd.—A copious eruption of herpes on right cheek and lower lip ; less tenderness behind ear ; much purulent discharge from meatus ; urine clear, and not albuminous ; two days ago deposited much uric acid, and contained a large excess of urea nitrate ; the urine in tube becoming half solidified with crystals.

Potass iodid, gr. iss. ;
Dec. cinch. ℥ss. *ter die.*

5th.—Is quieter, but there is much unsteadiness still ; pulse, 80 ; not easy to count. Temperature, 31° 7 (99° 8 F.) Weight, 45 lbs. ; urine, of twenty-four hours, 24 oz. ; sp. gr. 1·026 ; total urea, 340 grains ; total phosphoric acid, 27·32 grains. His father states that he had gastric fever two or three years ago, and that he has been subject to attacks of earache and discharge ever since.

Nitrate of silver lotion (gr. v., ad ℥iij.) in place of lead ;

Lin. iodi. post. aur. sinistr. ;
Extr. opii. gr. 1-6th in pil. *bis die.*

7th.—Is decidedly better ; hands much steadier.

10th.—Right hand more powerless, he has pins and needles sensation in it, but he moves both hands tolerably well, though by no means steadily ; the ear has got well, there is no discharge, and he hears the watch tick at about four inches.

Succi. conii, ʒj. ;
Dec. cinchon. ℥ss. *ter die.*

13th.—Much the same ; cannot hold his hands with fingers touching over his head (Gothic arch-wise) ; right hand weak, and speech very failing ; voice scarce audible.

Ferri. carb. saccht. ʒj. t. d. ;
Omitti. mist. conii.

17th.—Is much steadier, but speech remains feeble ; urine deposits uric acid.

21st.—Improving decidedly, but the voice is very weak, and he makes but little use of right hand ; appetite very good ; first sound at apex prolonged.

Pt. c. pulv. ʒss. *ter die.*

24th.—Is much better ; hands much steadier when raised above his head ; weight 50½ lbs., on 26th practises bowling a ball at another at some distance and aims well.

29th.—Doing very well ; urine deposits an abundance of fine crystals of uric acid spontaneously, reddens blue paper strongly; 100 C. C. of urine, (in acidity), 9.628 grains of oxalic acid.

July 6th.—Weight, 52 lbs. without coat or boots; can hold his hands touching quite steady over his head; doubtful systolic murmur at apex; pulse compressed by 174 grams; 7th urine, 16 oz. in twenty-four hours; sp. gr. 1027; total urea, 256 grains; total phosphoric acid, 24 grains; uric acid deposited spontaneously. To be O. P.

The duration of the disorder in this case may be reckoned at about eleven weeks. It was preceded by a period of failure of health without any definite symptom. There was no indication of the presence of rheumatism, nor much of the existence of any endocarditis; the prolonged first sound did not attain the development of a murmur, and was very probably produced by slightly imperfect or irregular action of the columnæ papillares. The question may be raised whether the disorder depended on aural irritation, which existed possibly in a semi-latent form before it attracted our attention. The lad did not improve at all until the aural disease was treated, and soon after that was amended, his chorea became amenable to remedies. To those who dis-believe in the treatment of chorea, this of course was merely the result of lapse of time, but as I cannot hold with them, I must moot the point with you. There is no doubt that inflammatory affection of the head, its bones or membrane, such as is relieved by local blood-letting, is capable of being a cause of chorea. Sir Thomas Watson tells us that the chorea has been found to become sensibly less severe, and very soon to cease on taking blood by leeches or cupping from the painful side of the head. Now our patients had certainly inflammation of the tympanum and mastoid cells, and it does seem to me very probable that this was the cause of the neurosis. But you may think that the persistence of the disorder, though somewhat mitigated, for some days after the aural affection had ceased disproves this connection. The answer to this rests upon an important general fact, viz., that it is very ordinary for a morbid effect to continue for a considerable time after the cause which produced it has ceased to operate. I have known a day's over fatigue induce distressing cardiac disorder, which continued for years, though the heart remained organically sound. Thus the aural irritation may have been chiefly concerned in producing the chorea, which once generated, persisted until the nervous instability was rectified by an appropriate remedy. Conium was fully tried in this case, and failed to accomplish anything. Several other remedies were given, but their failure is perhaps attributable to the insufficiency of the time during which they were used. Carbonate of iron, however, very soon approved its utility, and under its influence a very satisfactory recovery took place, during which his weight increased seven lbs.

The duration of the disorder in this case was nearly double what it was in the three first. They continued about six weeks, and this is reckoned by some to be about the usual time that uncomplicated chorea in children persists. But I have notes of a case under my own care, when the disease (uncomplicated in a child) lasted four months, and Dr. Fraser alludes to two cases of his own, where the period exceeded three months. I doubt exceedingly whether the duration of chorea cases is in any degree so uniform and ascertained, as to warrant our folding our arms and doing nothing to abbreviate it. In Case II. the urine was first analysed in the third week of the disease, when it was fully developed, but the quantity of urea was hardly excessive for a child, not quite five grains per lb. of bodily weight; the phosphoric acid also was not above an average amount. In Case V. the first analysis was made in seventh week of the disease, when it was at its maximum, the amount of urea was greater, amounting to nearly eight grains per lb. of body weight; the phosphoric acid amount was not perhaps excessive. In both cases the [illegible] of urea and of phosphoric acid lessened [illegible] during convalescence, though not very strikingly. The inference I am inclined to draw from these and other analyses (a) is that increased elimination of urinary constituents is an ordinary, but by no means a constant, occurrence in chorea. The temperature observations go to confirm the view usually held, that chorea is a non-febrile disorder, it was remarkable in Case IV. how much the temperature rose (about 5½° F.), when quinsy came on. The effect of conium in Cases II., III., and IV., certainly was remarkable, to all appearance it controlled the disorder positively. In Case V. it was quite useless, both when given at the time of, and after the aural disease. In Case IV. the striking alteration in the mind and temper, which coincided, to say no more, with the administration of conium surprised me very much. The girl was perverse, mischievous, and semi-maniacal, before the drug was given, and afterwards was quite rational and well behaved. This fact is I think highly interesting, not only as regards the action of a remedy, but also as bearing on the nature of chorea. Some have spoken of chorea as "insanity of the muscles," we might rather say of motor centres, but in such instances as that of E. W., the expression transferred to the intellectual centres and emotional seems no longer figurative, but literally exact.

The chief points illustrated by the above cases which I commend to your attention are:—

(1.) The tendency of chorea proper—motor centre disorder—to be attended with an analogous state of the emotional, or of the intellectual, centres.
(2.) Its liability to occur in a modified form, and to be complicated with quasi-epileptic attacks.
(3.) The absence of rheumatism or definite endocarditis in all the cases.
(4.) The varying duration and causation of chorea.
(5.) The certainty that the same remedy is not suitable to all cases.
(6.) The increased excretion of urinary solids which not unfrequently occurs in chorea.

◆

A FEW REMARKS ON THE TREATMENT OF ASTHMA.

By John C. Thorowgood, M.D. Lond.,

Assistant-Physician to the Hospital for Diseases of the Chest, Victoria Park.

Experiments made by Paul Bert, Tranbe, and others, have shown that one result of irritation of the pneumogastric nerve is to cause contraction of the lungs and arrest of respiration; this arrest being more easily produced during expiration than during inspiration.

The lungs themselves contract just as does a sponge when squeezed in the hand, and so long as this contraction continues so long does the paroxysm of asthma and difficult breathing exist.

Prolonged expiratory efforts, as by a violent burst of coughing or a fit of laughter, are very apt to determine a fit of spasmodic asthma in one predisposed thereto, illustrating the fact shown by the experiments above alluded to, that arrest of respiration from closure of the lungs is more easily produced during expiration than during inspiration.

This will be enough of the pathology of asthma for my present purpose, since I have shown what a fit of asthma is in itself, and that it may be caused by irritation of the pneumogastric nerve.

Now, this pneumogastric nerve, as its name implies, supplies nervous filaments not only to the lungs but also to the upper part of the alimentary canal—viz., the pharynx, œsophagus, and stomach, and hence any irritation of these parts may show its effects in the form of contracted lungs and asthmatic paroxysms.

These are matters tolerably well known and understood, and yet in the practical treatment of such a complaint as spasmodic asthma we seem hardly to get that help from this physiological and anatomical knowledge to which we are fairly entitled.

(a) Transactions of Clinical Soc., Vol. iv., p. 83.

Efficiently to treat spasmodic asthma in its various forms we must recollect that we are dealing with a pulmonary neurosis, and endeavour to allay any irritation of the pneumogastric nerve as much as lies in our power.

Commonly we find in a paroxysm of pure spasmodic asthma that medication of those filaments of the pneumogastric that go direct to the air tubes and lungs by means of certain fumes and vapours, as, for example, burning nitre paper, or the smoke of stramonium or tobacco is sufficient to relieve the spasm and cause relaxation of the air tubes, but these are at best but temporary expedients, and naturally patients and physicians seek after some means of cure likely to be more radical and permanent in its effects.

So far as the experience of the present writer goes this may be found often in treatment carefully directed to the stomach and liver in the first instance; and, secondly, in the use of certain tonics that have in some way or other a permanently curative power over neuroses of the lungs and heart.

In observing patients with various chronic maladies of the lungs, we often have brought before us the sympathy that exists between the pulmonary and gastric organs. For example, E. J., a man among my out-patients at Victoria Park Hospital, has been almost from childhood liable to cough and difficult breathing, and he remarks that he has always noticed any overloading of his stomach with food to be invariably and at once followed by increase of frothy expectoration.

Again, Mr. B. has had asthma for twenty years, and has taken all the most approved remedies for this complaint, under most able advice, with very little real benefit. He has, however, no trace of structural disease about the heart or lungs, while symptoms point very decidedly to irregular action of the liver and stomach. The occasional use of the *Cigarettes de Joy* and a mild dosing with Carlsbad salt, brought this gentleman to a degree of freedom from asthma that he had not enjoyed for full twenty years.

Much stress is very properly laid in books on asthma on the patient's diet. He must not dine late, and certainly must never indulge in supper. Sound and sensible as this rule is, yet I believe the practice of eating nothing after midday is carrying things a little too far in most most cases. A state of exhaustion may be induced which always increases any kind of nervous irritability, and further than this, the long-continued innutrition may later in life lead to actual structural change of a degenerative kind in the lung tissue.

I find in practice that a small sandwich of bread and meat, or sometimes a cup of bread and milk, is very grateful to a hungry asthmatic in the evening, and in no way injurious.

The medicines that have more or less credit in the cure of asthma are almost "legion," the reason being that some fit, as it were, one end of the pneumogastric, some another. Thus bismuth and hydrocyanic acid are of great value when the neurosis is of gastric origin. Carlsbad salt, nitric acid, and at times small doses of mercury, are all unmistakeably curative when the hepatic system requires relief.

Other remedies, such as ipecac., belladonna, nux vomica, will cover a wider range of symptoms dependent on pneumogastric disturbance, while if we have reason to suspect a gouty or rheumatic diathesis as the root of the trouble, alkalies with iodide of potassium, sulphur, and arsenic will be the remedies indicated. While, then, we certainly have no "specific" for the cure of asthma, we may, by considering the complaint in its wide range, as a neurosis of the pneumogastric, get some very satisfactory results from treatment.

The Obstetrical Society has published the regulations under which it proposes to admit women to examination for certificates of fitness to act as midwives.

SYPHILITIC DISEASES OF THE THROAT.

By Prosser James, M.D., M.R.C.P., &c.,

Lecturer on Materia Medica and Therapeutics at the London Hospital, Physician to the Hospital for Diseases of the Throat, &c.

Perhaps the most common form of syphilitic disease of the throat is the inflamed state of the mucous membrane in the secondary train of symptoms. The whole of the fauces are affected. Those who have studied the skin symptoms of syphilis, must have noticed the association of certain forms with the varieties in the affection of mucous membranes. This is an analogy similar to many others I have insisted on elsewhere. Thus with roseola, we meet with the dark red or purple of erythematous inflammation of the fauces. Swelling may in this form be considerable. The papular, squamous, and tubercular skin affections, accompany the elevated and well defined mucous patches. All the parts usually spoken of as the throat, may suffer simultaneously or successively in either secondary or tertiary syphilis. It is convenient, however, to make our distinctions between the several parts. The tonsils, uvula, and velum, mostly suffer whenever the pharynx is affected.

Acute pharyngitis may endanger life by giving rise to œdema, or purulent infiltration, but these cases are not often syphilitic, and even should the constitution be saturated with the specific poison, the immediate treatment of such accidents would be that appropriate for other cases.

Ulceration of the pharynx is more common in syphilis, but this too occurs from other causes, and is often to be considered strumous, particularly in children. Ulceration of the pharynx, tonsils, and velum simultaneously, is almost always (some say invariably) due to syphilis. Its nature is made clearer by the history and other effects which appear about the same time, as the skin eruptions, nodes, pains in the joints and limbs, &c. Great loss of substance may occur, but under large doses of iodide of potassium, the ulceration is arrested, the edges granulate and contraction takes place, and it is surprising how small an aperture may eventually remain, to what might have been feared. Eventually, operative procedures for this may be undertaken, or the skilful dentist will provide an artificial palate. Adhesions sometimes occur between the velum and other parts, closing the natural passage between the posterior nares and fauces, necessitating surgical interference at the proper time.

Laryngeal disease.—Nearly half the laryngeal cases in hospital practice are to be traced to syphilis, but in private practice the proportion is much smaller. In secondary disease, the mucous membrane may be affected much in the same way as that of the pharynx and fauces. Indeed, the disease may run along the mucous membrane by mere continuity of structure, and the same analogies may be noticed in reference to the skin diseases. The symptoms are not necessarily severe, there may be no dyspnœa, and no cough, but the peculiar hoarseness of the voice is mostly present. Sometimes laryngeal symptoms will come on after the fauces are quite well, and both patient and physician had hoped that the throat would give no more trouble. Ulceration may take place in the secondary period, but is not usual, except in bad constitutions. Even then it mostly occurs only in small patches, and is not intractable, but it leaves the larynx sensitive and more liable to attack in the next period.

Laryngeal ulceration, as a manifestation of tertiary syphilis, is more common and more serious. It may begin in the mucous membrane or in the deeper tissues. It may be single or multiple. It is easy to discover with the laryngoscope. The epiglottis is often the first part to suffer, and on the first examination this is often seen to be destroyed to a considerable extent. One patient was seen on laryngoscopic examination to have a hole in the epiglottis, as if it had been drilled through. Usually the disease is confined to the edges, which are rough, jagged, and, so to say, eaten away. The ulceration spreads, and where holes have been made they coalesce. It may thus occur that portions of the cartilage are almost detached and hanging by the sound portion, they may drop down into the larynx and give rise to paroxysms, similar to those caused by an elongated uvula, or a foreign body. A little later the vocal cords, both true and false, are attacked by ulceration. The laryngeal symptoms are then more marked, but the diagnosis in both cases is made by the laryngoscope. Generally speaking it is still later before the mucous membrane over the arytenoid cartilages is involved, and this is worthy of remark, inasmuch as in laryngeal phthisis this part is attacked, as a rule, earlier than the vocal cords.

Later the cartilages may become diseased, and then we may be called upon suddenly to combat the paroxysms caused by a portion of necrosed cartilage having become detached, and acting as a foreign body.

Even in grave cases of tertiary syphilitic disease of the larynx the symptoms are not necessarily severe. The voice is altered or lost. The impaired voice of syphilis is very characteristic. Dyspnœa may be present from the slightest embarrassment to the most distressing degree. If it occur in paroxysms there is cause for much anxiety. Difficulty of swallowing is mostly present when the epiglottis is affected, but it is surprising how much this organ may be injured without the patient complaining of this symptom.

The diagnosis must be made by aid of the laryngoscope, but the history and other points ought not to be left out of account. The dusky purple hue of the larynx in syphilitic erythema contrasts strongly with the brilliant red of catarrhal inflammation; but then it is to be remembered that at all stages of syphilitic disease the larynx is very liable to be attacked by common inflammation. Acute laryngitis occurring in the course of syphilitic disease is very serious, and the spasms that then occur may be fatal, unless met with the promptest treatment.

The tubercular and papular elevations seen in syphilis are not much like the granular and even dotted appearance met with in phthisis, and there are moreover in this disease other very characteristic lesions seen in the laryngoscopic mirror; they may, however, possibly be mistaken by the inexperienced for polypi. This is more likely to occur when the elevations are considerable enough to be called condylomata. These are not uncommon in syphilis, and sometimes look like warts, while at others they resemble to some extent various laryngeal growths. It is, perhaps, worth while to mention this, as syphilitic elevations easily yield to constitutional treatment, though they may set up ulceration.

(*To be continued.*)

◆

LECTURES ON THE TREATMENT OF CHRONIC SKIN DISEASES,

DELIVERED AT

ST. VINCENT'S HOSPITAL,

By E. D. Mapother, M.D., Professor R.C.S.;
Late Examiner in Surgery, Queen's University.

Lecture II.

The moist eruptions of the skin which we shall to-day consider, belong either to the orders of vesicles and pustules in Willan and Bateman's classification, eczema and impetigo for examples. The French writers regard these diseases as the same, and as dependent on some ill-defined systemic state which they call "dartrous." They at least agree in being moist eruptions due to local causes.

Mr. Wilson also regards these and other diseases stages of the other. He defines eczema as "a chronic inflammation of the skin, attended with desquamation, exudation, and pruritus." His "essential varieties" of eczema are "erythematosum, papulosum, vesiculosum, ichorosum, pustulosum, et squamosum."

In all, the sebaceous glands are excited and the quantity of their secretion augmented by the greater flow of blood through the capillaries of the skin.

Eczema (from *εκζέω* I pour over) is the most frequent of skin diseases, constituting over one-third of them, according to Wilson, and 2,527 out of 10,000 cases treated by Dr. Anderson in hospital practice and 348 out of 1,000 cases in private. Hebra states that 4,000 out of 6,000 cases were in males. We rarely see the rash early, but vesicles may sometimes be found in the first blush, or at the extending edge of the eruption. The most usual appearance is a red surface with fissures, which sweat out a thin fluid, or with thin yellow scabs into which the fluid has dried. So surprisingly vascular is the skin with a great plane of interwoven capillaries that we cannot wonder at the copious exudation of the serum of the blood which occurs in eczema. Like catarrh in mucous membrane, it is the most common form of cutaneous inflammation. It is essentially a dermatitis, or catarrhal inflammation of the skin, and it is not contagious. The thin albuminous, or rather fibrinous, fluid, for that substance is shown by its stiffening linen when it dries is enough to distinguish the disease from all others. The deeper layers of the cuticle, including that lining the sweat ducts appear most involved. The most common seats are the scalp and ears, the face, the legs, and the forearms. Its appearance differs greatly in each of those situations.

On the head it is more pustular, and the term impetiginodes is often added to indicate this. The great vascularity of the part, notwithstanding the pale colour of the surface and the irritation due to the growth of the hair, I think account for the substitution of the suppurative for the exudative process. From these children you may learn all the features of the disease. Pediculi are nearly always present, and they fret the skin very greatly. A smell like that from the goat often arises from decomposition of the sebaceous fatty matters, giving off of caproic acid. The glands in the upper and back part of the neck always enlarge, but I have never known them to suppurate, which tends to show that the disease is not essentially scrofulous.

The disease does not cause baldness, but in some adult patients the hair which grows is grey. Many of the cases regarded as *plica polonica*, are said by Hebra to be eczema, in which the hairs are matted by copious discharge.

I feel sure that eczema, although the most common is the disease of the skin the most difficult to diagnose, unless you see the whole of the eruption, and get safe information as to its duration. This girl for instance, has patches on each elbow which are very like psoriasis, but the upper arm and axilla on the left side are the seats of the true moist eruption.

Eczema on the face is the most painful, as the itching and burning are intense. The high degree of innervation and contact of the air explain this. There is a good deal of œdema, especially in the lower eyelid, and occasionally slight conjunctivitis.

The scabby mass termed crusta lactea, is an eczema of the lower eyelid and cheek, excited usually by the scalding tears which flow over so profusely in strumous ophthalmia.

The disease on the legs gives rise to the state called "weeping leg," an affection most common among the pensioners in Chelsea Hospital. These old warriors patiently bear this ill, for they believe, and with some reason, that a graver one, such as diarrhœa or bronchitis, is apt to supervene on its cessation. Hebra denies this kind of metastasis, and urges us to cure eczema in all places as soon as we can. He uses baths so freely that the rest of the skin acquires increased activity, and any determination to internal organs is prevented. Varicose veins, and the consequent congestion leads usually to this eczema, as well as to some other eruptions on the legs, and elevation is therefore an all important element of treatment. It soon reduces the infiltration of the areolar tissue.

The forearms and hands are often the seat of a kind of eczema, especially apt to occur in grocers, confectioners, and others handling sugar. In the soft brown kind of this substance a mite, the acarus saccahri, is often found, and it has been accused of originating the disease. The heat to which the bare arms of confectioners is exposed may have something to do with the causation of the rash, and I have often seeen it on the hands and forearms of cooks. It this situation it often takes on the form of eczema rubrum, the most inflammatory form, as indicated by the bright red congestion locally, the height of fever, the fibrinous excess in the blood, and the utility of lowering medicines.

The deep fissured disease on the palm of the hand, often called psoriasis palmaris, has more the features of eczema, and if we remember how thick and non-pliable owing to want of sebaceous glands the cuticle is there, we cannot wonder at the peculiar disease. This rimous form occurs on other places, according to Dr. Anderson.

From birth, when the region of the umbilicus may be the seat of eczema to the other extreme of life the disease occurs. The eczema of infants is often treated by feeding the child from the "Mamma" bottle, or by the getting of that most difficult of all wants, an honest healthy wet-nurse. The scalding about the groins and thighs of children (intertrigo) I regard as eczematous, and due to friction or irritation by the child's urine. Grooms often get eczema about the groins and thighs, as in the case now in St. Patrick's Ward, and shoemakers who sit so long with the thighs together. We said something in our last lecture of the affection which is probably parasitic, and is very common in India. Other local causes are the strapping of ulcerated legs with plaster, especially if there be varicose veins and an irritable constitution; soda and soap, if frequently applied, as among washer-women, contact of lime as amongst builders' men, the use of cosmetic powders, paints, and washes, the wearing of stockings dyed with auiline, and lastly, though not less frequently, the action of the sun's rays.

The rubbing in of irritants, such as croton oil, will cause eczema, and in different sites its appearances vary most remarkably, and thus is illustrated the usual varieties of the disease. The rash brought out by sulphur baths and named *la poussée,* as well as that following hydropathic treatment, are eczematous.

The constitutional condition necessary for the origin of eczema is termed "*dartre*" by the French, but it is hard to understand what it means.

It certainly seems to be sometimes hereditary, and has tendencies for spreading and for recurring, and another argument in favour of its constitutional character is derived from the fact that diarrhœa, bronchitis, and leucorrhœa in the female break out on the cessation of the cutaneous exudation.

I do not think it is necessary for us to alter the definition of eczema, which Willan eighty years ago gave us, viz., "An eruption of small vesicles on various parts of the skin usually set close or crowded together, with little or no inflammation round their bases, and unattended by fever. It is not contagious."

In the index of Professor Wilson's work on "Ekzema" forty-eight adjective terms follow that name, and its combination with twenty-five other diseases are noted besides.

The division of acute and chronic is often made, but I think the one is but a stage of the other.

In describing this and the other common forms of skin diseases, I do not delay you about the diagnosis of each affection, as I hope the short sketch you have heard will enable you to recognise them, especially as you have lately seen them all. Great space is occupied in books about skin diseases by the reiteration of the characters of many for the diagnosis of each.

Eczema mercuriale I have not seen, nor have I ever heard of a well marked case, for I regard the rash brought out by the rubbing in of mercurial ointment quite different from the disease described by Sir T. Moriarty and Mr. Alley in 1804. The latter gives the following description:

"As the Hydrargyria has been mistaken for other diseases, the following brief recapitulation of its most leading features is subjoined.

"1. The eruption is for the most part, at first vesicular.

"2. The fever and eruption are generally synchronous in their appearance.

"3. Exfoliation of the cuticle usually takes place, about four days after the appearance of the eruption, and is commonly preceded by soreness of the throat and fauces.

"4. In severe cases, blisters, sometimes large vesications, precede desquamation. The cuticle, in such cases, cracks, and forms fissures; and the odour of the exudation from the surface is strongly characteristic of the disease.

"5. The presence of the delirium ferox has never been witnessed, however considerable the inflammation and tumefaction of the external parts of the head: nor has the head appeared engaged, excepting where the debility was extreme, and the exudation from the surface profuse.

"6. When the cuticle desquamates, the parts underneath appear red, as before that occurrence.

"7. The disease is never fatal, unless secondary fever supervene.

"That the production of the troublesome and dangerous affection just described is attributable to the employment of mercury in peculiar habits, the following facts tend incontrovertibly to confirm. 1. Mercury aggravates the symptoms of the complaint, when produced. 2. By discontinuing merely the use of mercurial preparations, the progress of the disease will often be suspended. 3. The disorder may be reproduced by an incautious or too early recurrence to the exhibition of the mineral. 4. Somewhat similar cutaneous affections are the consequences of other irritants beside mercury; and those also admit of relief from the removal of the exciting causes.

"A peculiarity of habit, or a certain state of the skin itself, has been supposed as predisposing to this disease, and appears, indeed, to be actually requisite for its production."

We never see the disease now, and although I have investigated the effects of mercury on all the mirror makers in Dublin I got no trace of it (MEDICAL PRESS AND CIRCULAR, 1866 and 1870). Nearly all Alley's cases were in Lock Hospital patients, whose dose of mercury was counted by the number of pints of saliva discharged daily. Some of the cases may have been really venereal rashes.

Internal treatment is needed in the earlier and inflammatory stages of eczema, and it should consist of some salt which will act on the entire alimentary mucous membrane, and on that of the kidneys as well. In private practice, I select the effervescing citrate of magnesia, two teaspoonfuls in half a tumbler of water every morning, and if there be any gouty diathesis, half a drachm of citrate of lithia is added.

In hospital, tartrate of potash and soda is used instead, or for the first dose, forty to sixty grains of the compound jalap powder.

Drs. Wilson and Fox tell us that eczema is a disease of debility; but this is not evident from their descriptions of the affection, nor from their recommendations for its cure.

I know of one case of highly inflammatory general eczema recurring yearly, where bleeding from the arm alone gives relief. In this case when the eruption has been out some two or three weeks, the sulphur water of Lisdoonvarna has been found on three occasions most serviceable. During two visits last summer at this admirable watering-place, I saw very many cases of obstinate eczema, which were much benefited by the sulphur water. So were cases of acne and psoriasis. There were no baths, however, but they are likely to be erected before next season. Iodine, arsenic, phosphorus, and such drugs, which are called alterative, I have never tried, because we do not understand their action, and they have not been of any use in my hands.

If inflammatory symptoms last in chronic cases, I have sometimes continued the salines above named daily for many weeks. If there be much itching or pain at night, fifteen to thirty grains of that admirable medicine, chloral should be given. The only alteration in diet which is needed is a full allowance of vegetable food, especially those which are eaten raw, salads, celery, and the like, for thus the potash salts are ingested. From boiled vegetables, they are abstracted. If, indeed, the patient has been taking beer, wine, or whiskey in excess, the excitant must be diminished or checked altogether.

The best of all local remedies, and the only one wanted in many cases is, an abundance of pure soft water, with which the part should be bathed thrice daily. It should be dried by pressing down a dry cloth, not by rubbing. Hard water is irritating, but it may be softened by boiling, and the addition of bran, flour, or other mucilaginous matters, which further abstract the lime salts. For hospitals, Clarke's process of adding fresh lime, which seems so paradoxical, should be adopted for softening water. Our Varty water is excellent for this purpose. General baths are of essential service, as may be likewise said in the case of all other chronic skin diseases, for they cause the healthy surface to compensate for the suspension of the cutaneous functions in the diseased part.

The tepid shower-bath is the best in eczema of the scalp, and should be used twice daily.

Dozens of external applications have been successively recommended, and I will mention them to you, although I do not believe much in any of them, save those containing carbolic acid. Its ointment (one drachm to the ounce of lard), I always use in cases where the disease attacks the scalp, as it checks fœtor, and keeps off pediculi, but it has probably no specific action. Eczema marginatum shows plenty of the trichophyton in its scales, and carbolic acid would kill it. The fat softens and removes the scabs, always a necessary step, and protects the sore skin from air. It should be freely used thrice daily, and the head kept then covered by a flannel cap. The oil of cade distilled from juniper wood has been greatly vaunted, as also has a mixture of equal parts of tar, soft soap, and methylated spirit. The latter bears the all-important recommendation of Professor Hebra.

Bishop Berkeley's pine-tar water had its advocates for many years, and no one can read the work of our most illustrious countrymen, without astonishment at the suggestions about the curative effects in cases of itch, prurigo, lepra, and tinea, and its disinfecting power in contagious diseases. Like other discoverers, he exaggerated its virtues, but not until he had fully tried it on his own person, for he tells, "I have myself drank above a gallon of tar-water in a few hours, and been cooled and recovered from a fever by it."

On the arms and legs, especially if the surface be red and tender, weak lead-wash from one to two drachms of the liquor plumbi to the pint, applied with a bandage, is most soothing and useful. I have seen it successful in scores of cases with Dr. Neligan. Hebra praises highly the following ointment, when the disease attacks the flexures of joints :—

℞ Olei. oliv., ℥xv. ;
Litharg, ℥iij., ʒvj.
Coque et adde. olei. lavand, ʒij.

Tannic acid ointment, and cod-liver oil, have been extensively used, and for the relief of itching, watery extract of opium and chloroform have been advised. Hydrate of chloral would be chemically compatible with some lotions and ointments, and would afford more continuous ease from this annoying symptom.

The frequent form of the disease in the palm of the hand characterised by deep fissures radiating from the wrist towards the fingers, is most stubborn to treatment. Slight cases are relieved by soaking with glycerine ; but, in very chronic cases, the cuticle must be softened by the wearing of an india-rubber glove, and steeping with bran. The fissures may then be touched with melted carbolic acid.

When the scalp is affected, the hairs must not be shaved off, but clipped short every week or two with good broad bladed scissors. The semi-purulent scabs should be removed by poulticing with bran, and stupeing with the water which has boiled that very useful material. If the case is watched for and treated on the first day or two of its appearance, carbolic acid ointment will suffice to check the eruption ; for example, I thus successfully treated a nobleman's son last September, whose brother had developed eczema on the scalp, and as it was erroneously supposed the disease was contagious, the second lad's scalp was daily examined, and when a patch an inch in diameter was developed, I saw the case. The avoidance of any local irritant which may have excited the eruption, is an evident indication.

Prof. Erichsen, in his excellent work "On the Scalp," recommends strong lotions of sulphuret of potassium, which would act by the evolution of sulphurous acid. From the success of this agent and of carbolic acid, such decided parasiticides, many forms of eczema capitis may be due to the development of some parasite.

Dr. Fox opens his section on *treatment* as follows:—"Eczema I hold to be of the nature of catarrhal inflammation. This implies debility. It is highly unsatisfactory to consult books about the treatment of eczema. One gets very little from them ; I shall not follow the bad example hitherto set of giving a general *resumé* of the action of remedies." With much respect for his original and clever book, I do not think the chapter from which the above is extracted, is exempt from the faults he finds with other works, and if we are ever to free the treatment of skin diseases from the empiricism which now shrouds it, it must be by investigating scientifically the action of various drugs and appliances,

There is scarcely a medical or surgical, constitutional or local lesion which you may not find on a patient with eczema, and it must be treated before the eruption will yield. This affords much reason against the separation of "dermatology" from general practice. However, so tedious are many cases that, as Dr. Neligan well says, "success must be earned by the joint patience of patient and physician."

In this hospital we have such assiduous care on the part of the Sisters of Charity in the giving of internal and application of external remedies, that I find skin diseases are more rapidly cured than in private practice, notwithstanding the ability of the latter patients to pay for the best aid they can get.

Prickly heat, the lichen tropicus of Willan, is generally described as a form of papular eruption. During my tour through the United States in the summer of 1870—an unusually hot one—I saw many cases, and in nearly all vesicles, in one case bullæ were present. Some persons were entirely exempt, and they were mainly daily tub-bathers and lightly dressed persons, who thus had habituated their skin to variations of temperature. It seldom was seen on the face, neck, or hands, the parts oftenest washed. At night it was so distressing that sleep was impossible. Tepid baths are most useful.

In Ceylon, the natives treat prickly heat by cutting a lime fruit in two, and rubbing each other down. The rashes excited by mosquitoes are often eczematous. They were observed at Blackfriars Dispensary in the summer of 1870.

Impetigo, as I have peviously told you, is not a stage of eczema, but a disease primarily pustular, and more acute, and more curable. The pustules appear in two or three successive crops, as small distinct ones, but they soon coalesce, and bursting, the pus dries into a greenish dark scab, aptly compared to candied honey (hence Alibert's name for the disease, Melitagra). There is some little heat and itching, but rarely any fever. When the crust falls off, a red stain without any abrasion remains on the skin for some weeks, and the derma is thickened and hardened, so the seat of the disease is far deeper than the cuticle. The pustules occasionally contain a little blood, especially near the edge, where slight ulceration may appear. In the MEDICAL PRESS AND CIRCULAR eight years ago I published notes on a case of most severe impetigo, in which very high pyrexia existed, but in which the disease subsided in four days without any local treatment save poulticing. Willan and his very many annotators, state that impetigo "is not accompanied by fever."

Young persons from the period of second dentition to that of maturity are the subjects of impetigo. It is rarely seen in those over thirty years of age, and then in those who have a peculiarly thin skin. I do not believe that any cause in the system of the patient, or in the external influences he may be subjected to, has been shown to be causative of the eruption. I have seen it often in female servants lately arrived from the country, and who had got more animal food than they were accustomed to.

The disease is usually non-contagious, but Dr. Fox has described a form which rapidly spread among the patients of the Farringdon Dispensary. The only sensible character by which the disease may be distinguished from the usual form is the appearance of vesicles at the beginning. The *Lancet*, of November, 1871, contains the following paragraph:—"We understand that a form of skin disease, the exact cause and nature of which were at first somewhat disputed, has lately appeared among the men belonging to a battalion of Foot Guards stationed at Dublin. As many as 100 soldiers are stated to have exhibited manifestations of the disease, which is local in its nature, and unattended by any constitutional disturbance. The affection consists in the appearance of numerous small vesico-pustules about the scalp and face, which soon dry up and scab over. . . . . The outbreak in the Foot Guards originated among the children while the battalion was stationed at the Curragh, and the disease subsequently spread to the soldiers. In one or two cases its auto-inoculability was evinced by the fact that some spots appeared on the skin of the arm from the head having rested on this part during sleep. The old term 'porrigo' probably comprehended this affection, but this term was not very definitively used."

Some of these facts I was kindly allowed to verify, but I await with interest a full account in the next Army Medical Blue Book. Its diagnosis from cow-pock must be fully established before it deserves to rank as a new disease.

The division of the disease into I. figurata and I. sparsa is not needed, as the former is but a stage of the latter.

Its characters vary on several parts of the body. The face is by far the most frequent site.

If the scalp be the seat of pure impetigo, that is a purely pustular eruption different from eczema impetiginodes, I have not seen it.

Impetigo is said to appear alone in scrofulous subjects, but I cannot from my experience assert that any peculiar diathesis is connected with the eruption.

I know of few diseases which require less treatment than the one we are now considering. If a purge be given to lower the inflammatory action, if the scab be stuped and poulticed off by linseed meal, and if carbolic acid ointment be kept smeared for a week after, the case is cured.

I must acknowledge that I have seen a few slight cases which for three weeks had not been subjected to any treatment, and yet they got quite well as soon as the scab was removed.

If there be much soreness round the scab, a mixture of equal parts of olive oil and the liquor of sub-acetate of lead smeared over the part soothes it and excludes air.

Acne, or acme, as etymologists call it, from ἀκμή, maturity, as it usually appears at that epoch, is an inflammation of the sebaceous glands. If they merely increase their flow you have seborrhœa, but if they have their openings in the hair follicle blocked, the acne indurata appears. If this condition becomes chronic, with red bunches of capillaries tending to the little hard masses, the acne rosacea results. Paler and larger heaps of sebaceous matter swell out the cuticle, and they are called comedones. I have seen them largest on the scrotum. On the face the opening of the follicle is generally plugged by black dirt. Wens, or steatemata, as Sir A. Cooper proved, have a similar pathological origin, rudimentary hairs being, however, often developed in them. The rare disease, molluscum, is of a very similar nature, but the sebaceous masses project more, becoming even pedunculated and they are softer. You are aware that in the sebaceous mass which you can squeeze from the follicles near one's nose a little animal, the steatozoon, can be often, perhaps once in five persons, found; but they are far more numerous in acne subjects. It was in 1841 found by Henle in the ear glands, and soon after by Simon in the ordinary sebaceous glands. They lie with the head inwards, and as many as twelve have been squeezed from a follicle in a greasy-skinned person.

Acne is in the beginning nearly always papular, and often it is so throughout. This persistently papular form, or that with few suppurating papules, is seen in both sexes about puberty and the development of the sexual functions, and their abuse in the case of young men have much to do with it. The red variety of acne often begins on the face of females about the period of the cessation of the menses. If pustules fully form, they remain discrete.

The face is by far the most common site, especially of the indurate kind, or stone pock, as it is popularly called, but I have seen acne on the scrotum and groins. In these places the sebaceous glands which we have seen are its anatomical location, abound most, and are especially diseased. The face is highly vascular, and as we learn by the phenomena of blushing and pallor, its capillaries are readily and rapidly influenced by mental emotions, as well as by changes of temperature. Such conditions, as well as the flushing of the face by frequent alcoholic stimulants, are believed generally to be the most active causes. However I have seen acne in both male and female teetotallers, the former students who had the bad habit while reading of sitting before the fire with the head down, and the latter girls who had been foolish enough to use powders, paints, and other cosmetics.

Alcohol, by flushing the face, promotes the disease, and what are vulgarly called "grog blossoms" are spots of acne. Professor Wilson says:—"The physiognomy of the disease is made familiar to our minds by the words of Shakespeare, when he tells us with regard to Falstaff, that

> "His face is all bubukles, and whelks, and knobs, and flames
> of fire."

And in a few words the rosy spot may be said to be a protest of the fifth pair of nerves against ill-treatment received by the gastric portion of the eighth." The back of the neck and shoulders, after the face, is the most frequent site.

Spring is the time of year most favourable for its eruption, and it often returns for several successive springs.

As you may imagine, this disease causes great distress of mind, especially in the case of patients of the fair sex, often appearing just as they are about to be "brought out."

No special medicine is of use in acne, but several may do good, if any prominent signs of ill-health be present. I have most frequently prescribed mild saline aperients, such as a drachm of citrate of magnesia, with a grain of iodide of potassium, every morning and night.

Two or three grains of citrate of iron and quinine may be substituted for the latter, if there be much debility or spanemia. It is, however, in most cases, a well defined form of hypertrophy, affecting the capillaries and sebaceous glands of the skin. The saline mineral waters are often most useful. In no skin disease are general baths of soft water more useful, although for the first few days they seem to aggravate the case.

The removal of any local or remote cause should be carefully looked to, more especially as regards uterine derangements.

Open air exercise, and a simple diet, into which raw vegetables and fruits should enter largely, are valuable aids to the cure.

The local means of cure which I generally use, for the slighter forms with seborrhœa is a wash made of 1 oz. of glycerine, a drachm of bicarbonate of potash, and 11 ozs. of water. It is to be sopped over the face with a piece of soft flannel four or five times daily, and the face is then to be bathed freely with cold soft water.

Soft soap which contains potash is also useful, and the black spots which fill the mouth of the hair follicle are best removed by it. The patent washes so often used by ladies are usually compounds of bichloride of mercury, and instead of being useful in the disease, are most dangerous and disfiguring. Washes containing alcohol or vinegar were advised by Celsus, but I have seen that they make matters worse by exciting suppuration.

The hard nodules in the more chronic form, require to be touched on the point with some caustic, and the acid nitrate of mercury is the favourite.

The red branches of capillaries around should be cut across with the point of a very sharp lancet, which should be inserted to the slightest possible depth. Ice cold water will check the bleeding and shrink the vessels, and then the blood in them clots, and the vessels will often be removed altogether. If proper pustules form the pus should be let out of each, with the point of a lancet or a needle thrust transversely through the cuticular apex.

Seborrhœa nigricans is the name given to a curious affection, in which a black oily matter exudes from the skin round the eyes. Under the name of chromidrosis. Dr. Foot in the *Dublin Journal*, February, 1866, gives a learned essay on this symptom, which often points to suppressed amatory feelings or disordered uterine function. One-ninth of the cases, however, occurred in men. The colour may be yellow or blue. The black colouring matter or melanin, was said in one case to have appeared in the stools, urine and matters vomited.

As the glands within the prepuce which pour out the smegma are identical in structure with the sebaceous glands you might expect they would also pour out occasionally a vitiated secretion. Hence, or more often by the retention of the normal secretion and its decomposition by the heat and moisture afforded by a long close foreskin, great excoriation and tenderness arise.

The sebaceous glands are engaged either primarily or secondarily in lupus, and that sad disease for this reason rarely appears except on the face, where they most abound. In the groin for perhaps similar reasons, lupoid ulceration is also seen. The patient now in St. Anne's Ward has the disease on the face and on the front of the wrist. By touching the edges of the ulcers with glacial carbolic acid melted, dressing the surface with carbolic acid ointment, and the giving of iodide of potassium and bark mixture, you have seen that this extensive case has been almost healed in a fortnight. Huile de Cade, of which the best is to be had from Aix-la-Chapelle, and many other tar preparations so long in vogue owe their efficiency to carbolic acid. Dr. Neligan's favourite caustic was the solid acetate of zinc, and I have often seen it most successful in his hands.

The discharge poured out in lupus seems undoubtedly to be irritating to the healthy edge, and the agents I have first mentioned may modify the action. Iodine, if given in such quantities as shall not disturb the general health, also modifies these products of disease.

Pemphigus is also another disease which was much more frequent after the famine of 1845-7 than now, and under the popular name of "burnt holes" it was well known in distant parts of this country.

Oval or round blebs from one-third of an inch to two inches form all over the body, but the belly and thighs are favourite sites, generally in crops of six to eight at a time. They are at first filled with clear serum, but in thirty or forty hours it gets yellow and muddy, and the cuticle bursting, scabs form. A scalding fluid, however, issues from the ulcerated surface under the scab.

The more acute cases are attended with sharp fever, appearing in paroxysms as each crop forms. A very fatal form, P. gangrenosus, was described in 1808 by Dr. Whitley Stokes. This usually attacks weakly children when recovering from eruptive fevers, and I have seen it usually accompanied by cancrum oris.

In a fatal case which was treated here four years ago, the patient was a girl of twenty, who had been up to the time of the eruption in perfect health.

The chronic variety is far more common and is often met with in old broken down, and ill-fed persons. Sir D. Corrigan, in August, 1869, saw with me a gentleman about forty, of fair health and habits, except that he was fond of late hours and heavy suppers. He had had two previous attacks in the preceding autumns. Blebs the size of a sixpence covered his entire skin except the hairy parts; starch powder dusted constantly over the surface, with bark and careful dieting were successful in a fortnight, and the eruption has not since reappeared.

There seems to be no good reason for the belief still entertained by many eminent authorities that some kinds of pemphigus are syphilitic. Its frequent occurrence in remote parts of this country amidst a poor but very moral population where venereal diseases are unknown, contradicts the notion.

The constitutional signs being uniformally those of debility, nutritious diet, alcoholic stimulants, and the bark and ammonia mixture should be our treatment. Hebra praises the continuous bath of which I have before spoken.

Locally, carbolic acid ointment would be useful in checking discharge and fœtor.

◆

NOTES ON PHTHISIS PULMONALIS, &c.

By R. Locke Johnson,

Visiting Physician to the Infirmary for Consumption and Diseases of the Chest, Margaret street, Cavendish square, W.

(*Continued from page* 482.)

Case VI.

James F., æt. 28, married; one child. Has worked in a biscuit factory three years; previous to which was an engine fitter in the employ of the Great Western Railway. Six years ago had gastric fever, from which he got quite well; but had from time to time, especially in the spring, pains in the head, sickness, and loss of appetite, lasting for three weeks or a month at a time, and preventing him from working, and obliging him to resort to medical advice. Blisters behind the ears were several times prescribed, and relieved him. Admitted 6th January, 1871. About three months ago took cold, which he has never shaken off. Lost flesh rapidly, but did not get weighed. Last month thinks he has gained rather than otherwise, and is better in other respects. The cough comes on every night, lasts a short time, and is relieved by expectoration. Never spat any blood. Sleep is disturbed, but better than a month ago, then he used to wake up with cough, ending in vomiting every night. Has lost an uncle and an aunt in consumption, both on the mother's side. Fair vesicular respiration in both infra-clavicular spaces. Left base prolonged expiration, and increase of vocal resonance. Pulse, 112; temp., 98½ under tongue.

℞ Tinct. camph. co. m. xx.;
Mist. quinæ., ℥j. ter die.

Jan. 9th.—Had an attack of diarrhœa last night. Severe fluid stools. The last about two to-day. Pulse 92, full, easily compressible. Tongue clean and red at edges, with slight fur in the centre. Feels tenderness over abdomen; increased on pressure.

To have warm milk, and ♏ xx tinct. op. at night.

12th.—Bowels now regular, and has somewhat revived.

18th.—Has had another attack of diarrhœa. Relieved by same means, and has been taking Tr. camph. co. sp. eth. nit. three times daily.

20th.—Complains of headache for the last two days. Feels weaker, and the mixture no longer relieves the cough. Yesterday was seized with vomiting, and brought up besides his food a quantity of yellow, bitter, fluid. Has not vomited to-day.

27th.—Is much the same, but complains of his nights being restless.

Pil. conii. c. j. o. n.

31st.—Still cannot sleep. Pulse and temperature remain same.

℞ Chloral hydrate, gr. xx.

February 2nd.—Infra-clavicular spaces equal, and certainly not dull. Behind right infra-scapular space decidedly duller than left, and vocal resonance proportionally increased. May say bronchophony in right side. Pulse, 112; temperature under tongue, 100. Slept well after the chloral, but not last night, it was not repeated. Says he used to lie only on left side, but now is indifferent.

To take the chloral every night, and continue the quinine.

This patient in the next few days picked up wonderfully. The chloral was continued regularly, finding relief to the cough, and obtaining good nights by it. He improved gradually, and left at the end of the month in unexpectedly good condition.

Case VII.

William B., æt. 30, married, no family; enjoyed good health up to two-and-a-half or three years ago, when he was employed as ticket collector on a railway, and took numerous colds, one after the other; has been three months in Brompton under Dr. Cotton, all the time getting better. Discharged seven weeks ago; then went back, and, therefore, recommended here; admitted 6th of April. Five months ago, before going into Brompton, his expectoration became streaked with blood, not much after admission there. There he gained 4½ lbs.; he has lost 1½ stone since illness; has lost one brother in consumption; his father died at 73; his mother died at about 40, her legs were swollen, that is all he knows of her illness. Has sat up in bed hours together in hospital "for want of breath"; now sleeps the best half of the night. There is hard breathing at the apices with prolonged expiration. There is evident dyspnœa and slight cough.

Ol. morrh. ʒij. bis. die.

10th.—Dyspnœa came on again in the night, last night and two nights before, expectoration thick and dark.

12th.—Dyspnœa returned at two a.m. on the 11th, and lasted till six a.m. Last night slept quite well.

Pil. conii. comp. ♏v. o. n.

14th.—The dyspnœa returned last night at five a.m. Lin. Tiglii to right subclavicular region.

Pil. conii. co. j. bis. die., Ol. morrh.

18th.—Dyspnœa has interrupted his sleep lately again.

Vin. ipecac., ♏. xx.;
Sp. æth. sulph., o. ♏ xx., inf. gent. ℥j.;

21st.—Breathing has not been quite so bad; and still has fits of dyspnœa.

23rd.—Last night dyspnœa worse than ever.

30th.—Has had another attack of dyspnœa.

May 5th.—Both apices, weak breathing, and prolonged expiration. The left a shade duller than right; left base also weaker, but not duller than right.

℞ Ammonii. iodidi. gr. iij..;
Ammon. Carb. gr. v., aq. camph. ℥j., t.

11th.—No dyspnœa since 30th ult., and feels pretty well.

June 2nd.—The iodide of ammonium and the carbonate of ammonia have been regularly continued. The attacks of dyspnœa have not returned. He is very much better, and leaves the hospital to-day at his own request.

Case VIII.

Bridget F., æt. 10, has been attending two months as out-patient. Admitted in-patient, April 10th. Very intelligent, and gives her own account of her illness with distinctness. Mother and sister died of consumption; father living, but some of his relations also died of consumption; has always been ailing, and had a cough and wheezing as long as can remember, especially first thing in the morning and last at night; worse in winter. Does not feel cold weather unless foggy. Long ago remembers, after running very fast, had a violent fit of coughing which ended in bringing up, she thinks, about a tablespoonful of blood. Always thin, and does not think she loses flesh. At present coughs a good deal in the morning of thickish yellow phlegm. The girl is deformed, being pigeon breasted, while the scapulæ projects. The supra and subclavicular regions are hollow as if sank in; and she looks strumous or ricketty. The spine is straight, and there is no distinct history of effusion. Appetite good; but never ate a potatoe in her life as feels they would make her sick; no night sweats. Bowels three times a day, watery with much pain; tongue clean. Meat diet, one egg, milk.

℞ Pulv. dov. gr. j. o. n.;
Tr. camph. co. ♏ v. t. d., ex. aq.

On the right side, both front and back, moist crepitation. Also pain, and at intervals a distinct friction murmur.

12th.—Bowels better, once yesterday, twice to-day, but solid. Slept.

Repeat pulv. Tr. camph. co. ♏x.;
Tr. serpent. ♏xx. aq. ℥ss.

25th.—Appears to be going on the same, but there are now moist *râles* at both bases.

28th.—Cough better, much wheezing; expectoration purulent, streaked with blood, no pain; sleeps well; appetite good; nurse thinks gains a little flesh, herpes on lips.

May 5th.—Left apex slightly impaired, resonance, harsh respiration, almost tubular, left base increased, vocal resonance and some moist *râle*—a cooing rhonchus. Right extreme apex friction (?) sound, lower down moist crepitus, behind at base fine crepitus.

June 12th.—Has continued to improve steadily ever since coming to the hospital. Leaves to-day. There is now no friction sound, but both apices and both bases give moist *râles*. Nevertheless she has gained much strength; went about very cheerfully; eats well and sleeps well, and has no perspiration. Cough not very troublesome; not much expectoration.

21st.—Came to the hospital to-day, reports that her cough is more troublesome and she spits more.

HOMŒOPATHY.

By Gaetano de Pascale, M.D.

After all that has been written on homœopathy, such as it was discovered, formed, and almost axiomatically established by Hahnemann, I hardly dare to bring before the public some new observations on the absurdity of the system.

So great is the credulity of those who have put their faith in Hahnemann and his medicines, that they renounce all logical reasoning on the point, and citing the names of the most distinguished doctors of all nations (particularly those of England and France) is of as little avail as repeating to them all that has been written on the subject.

In Dr. E. Lee's work, entitled "Observations on Homœopathy," published in London, and approved by the principal literary and scientific journals, Hahnemann's doctrine is shown forth in its true colours, and faith must indeed have blinded the eyes of those who still persist in believing in such a system.

The study of medicine was born with man, and has progressed with him. Man living in society has sought to study and to alleviate his own and his fellow-creature's ailments. From a combination of symptoms, to the empirical administration of remedies and a diagnosis of diseases, he has passed to the development of occasional causes to pathological changes, and from thence to a more rational and discreet use of medicaments. All the world knows that pathological anatomy, chemistry, and the use of the microscope have concurred in giving to the art of medicine the name of a rational Science.

To my mind, there are only the disciples of Hahnemann, who, renouncing to listen to the voice of intelligence and reason, constantly thrust before you the practical facts which they have more or less badly observed, crying: "a fact, a fact," just as if they were saying a miracle, a miracle! The celebrated practician, Joseph Frank, was right, in defining homœopathy, to call it "a satire on human reason."

But let us lay aside reasoning for the present, and without losing our time in contending against the reproaches which homœopaths hurl incessantly at medicines and doctors called allopaths (I know not why this name has been bestowed on them), let us fix our attention for a minute on the first fundamental basis of homœopathy, *similia similibus curantur.*

According to the disciples of Hahnemann, homœopathic medicine first took its rise from the experience Hahnemann had of quinine; according to this doctor, this substance when taken produced in him symptoms of intermittent fever. The same happened with other drugs, which developed symptoms of maladies against which these latter had been recommended. Thus from thence, *similia similibus curantur*, from thence the first fundamental basis of homœopathy—"Homoios-pathos," similar sufferings.

It was only Hahnemann who observed the symptoms of intermittent fever after swallowing quinine, and other maladies in his making use of other remedies. No other doctor has confirmed the assertions of Hahnemann, as justly remarks Dr. E. Lee. And Hahnemann could only make his observations (let us keep to the name) allopathically, for Hahnemann was a doctor, and had not then begun to make use of homœopathic doses; he was at that time, too, in excellent health.

The falsity of the principle does not lie so much in the reasoning as in the facts; in the gratuitous assertion, or to speak more leniently, in the exalted fancy of the author of homœopathy. Everyone can easily experiment and verify the falsity of the principle of *similia similibus.* Hahnemann was the first who had the idea of diminishing the doses in medicine; and he observed that, in so doing, they did not lose their value, in fact rather acquired it, and he carried it to the extreme of infinitesimal doses.

The infinitesimal dose, according to Hahnemann, is not to act of itself, but its diminutive strength is to be developed by trituration if it be a solid medicine, or by shaking if it be liquid.

So much has been written and spoken against drops and globules dissolved in a large quantity of water, to be taken by small spoonfuls, and against boxes of globules swallowed by children, etc., that I hardly dare to call on that oft-repeated word, *good-sense*, in order to see all the absurdity of the ingenious conception of Hahnemann. The new disciples of Hahnemann say it is not essentially necessary to keep to the small doses; that depends on the wish of the doctor, but the essential is the *similia similibus;* and the homœopathic doctors in Germany, and more still in America, belong especially to this category; making use of concentrated preparations, as for instance doctors make use of Foler's solution.

The homœopathic doctors have obtained in favour of their system those members of the crusade who preach now-a-days against medical science and the abuse of bleeding (and polypharmacy), and they also attribute to themselves the honour of the progress which medical science has made; but that is an error, for it is but too evident that the progress made by it was without the aid of homœopathy, as the medical art, having always taken strides forwards, and being subject to changes before the time of Hahnemann, will never stop on the road of progress.

As a proof of what I have been saying about polypharmacy, I will repeat the words of the celebrated Dr. F. Redi, which are to be found in the works of the no less celebrated F. Puceinotti. Redi used to say, when prescribing two or three different medicines for one patient: "One at a time; you must never mix so many things, which we doctors order at one time; you do not find our prescription long enough if you cannot measure it by the yard, and are anxious to mix all those drugs, which are frequently sent us from all parts of the world with fine names, but which only serve to deceive some *povero cristianello.*"

Another, a new and simple system, but which to me is more unintelligible than that of Hahnemann, is the one of Count Mattei, of Bologna, who reduces to seven the number of medicaments in globules, of unknown substance, whose names are only anti-scrofulous, anti-feverish, etc., etc., and a few liquids named by him electric.

When once the falsity of the *similia similibus* is shown, and the absurdity of the infinitesimal doses proved, what more can I say about homœopathy, when I still see persons willing to be taken in by such a system. It must be one thing, that is, that apparently I have not enough intelligence, and more especially not enough imagination, to comprehend the grand ideas of the small doses, as do the disciples of Hahnemann.

I am certain, however, that those who call themselves homœopathic doctors, must have well studied the hygienic part of medicine, for they practise it very severely on their patients. They must likewise have a full, and at times I fear an exaggerated, confidence in the curative power of nature, which is so well appreciated by Sir John Forbes, in his "Nature and Art in the Cure of Disease."

As to homœopathic doctors, who in good faith are empiric observers of some favourable cure, such as sometimes happens to old village cronies, we can but pity their blindness; and those others again, who, according to the taste of their patient, treat either homœopathically or allopathically, I leave the reader to judge them; to me such a practice does not seem over honest, and the public ought to beware of them.

As to what concerns a doctor, who, after seeing a patient, will hold a consultation with a homœopath, that question has been so often discussed by the medical journals, that I will sum up the whole by saying, that it is inexcusable for any doctor to consult with another knowing him to be a homœopath, and when he does so, either under pretext of diagnosis or any other cause, I may venture to say, without being mistaken, that he only does it for the sake of the *auri sacra fames.*

◆

Hospital Reports.

METROPOLITAN FREE HOSPITAL.

Hæmaturia ending fatally.

Under the care of Dr. C. Drysdale.

(Reported by Mr. Kipling.)

Samuel Briscoe, æt. 73. Occupation a labourer, has been a good deal on the water as a waterman. In 1845 he had a testicle removed at Guy's Hospital.

Present attack came on six months ago with passing blood in his water, sometimes the water first passed was clear, and mixed with blood at the end; but at other times the blood was mixed with the urine from the commencement of micturition; occasionally he passed clots of blood; micturition was attended with a forcing pain and smarting after it was over.

Oct. 17th.—He now has all the above symptoms, with pain over his pubes, and in both groins. On a catheter being passed, a little obstruction is felt about the prostate which, on examination per rectum is found to be enlarged; urine acid containing one-third of a part of albumen, and on being examined microscopically it is found to contain blood corpuscles, but no casts.

R Potass. iodide, gr. v.;
Infusi buchu, ℥j., t. d. s.

Nov. 3rd.—Pain over sacrum and trochanter, as well as in the groins and over pubes; cannot sleep well at nights and has to get up every half hour to make water; urine still the same.

Pulse, 80; bowels confined; appetite good and otherwise seems in very good health.

R Potass. bicarb, gr. x.;
Tinct. opii., m x.;
Infus buchu, ℥j., t. d. s.

Mustard-plaister applied over sacrum which relieved the pain.

10th.—Much the same; appetite not so good.

R Acid nitric dil., m x.;
Infus. digitalis, ʒij.;
Aqua, ℥j, t. d. s.

21st.—Water seems a little lighter in colour; still in a good deal of pain; tongue white, furred; appetite bad.

23rd.—Not passed water since 5 p.m. yesterday, very great pain over pubes, but no distension of the bladder felt.

3 p.m.—Mr. Sheffield passed a No. 12 catheter but no urine came away only clots of blood which filled the instrument; and a substance like diseased mucous membrane of the bladder; he was put in a hot bath for half an hour; chloroform was given, and the catheter again passed, but with no better result; the bladder was injected with warm salt and water which came away again mixed with blood and clots; put to bed and ordered hot brandy-and-water.

24th.—Still passed no urine; wandering; but can answer questions put to him.

7 P.M.—Wandering worse, does not understand what is said to him; stertorous breathing; cannot take any nourishment as it all comes out of his mouth again without swallowing it; puts his hands over pubes as if in pain; face very flushed and swollen; pupils contracted; inclined to be violent.

7 P.M.—Passed a catheter again, but only about two ounces of blood and urine came away; seemed as if in great pain when the catheter entered the bladder.

25th.—Death at 4 p.m.

Post-mortem.—*Kidneys* enlarged; left, 7½ oz., right, 6 oz.; capsule slightly adherent in places; on cutting into them, a considerable amount of fat is seen surrounding the pelves which are also a little dilated; cortical substance pale; medullary rather red.

Ureters enlarged and dilated, so as to admit an ordinary sized lead-pencil easily; filled with urine.

Bladder is very small, containing one ounce of fluid; could not hold more than four ounces at the most; coats very much thickened, ¾ inch.

At the lower and posterior part, behind the level of the opening of the ureters, is seen an ulcer of the size of half-a-crown with irregular ragged edges and granulations upon it, nearly perforating the base; the mouths of the ureters are perfectly distinct from it though only two or three lines in front of the ulcer.

A piece of the diseased surface placed under the microscope presents the ordinary appearances of epithelial cancer.

Prostate is very much enlarged.

N.B.—There was considerable difference of opinion as to the nature of the case during the patient's life.

HONOURS FOR MEDICAL MEN.

Now that the injustice of excluding Medical men to so large an extent from the honours that other ranks enjoy has been admitted by the *Times*, we may perhaps hope that the occasion of the recovery of the Prince of Wales will be taken to honour, not merely individuals, but the Profession as a body. It would be a manifest wrong to many for it to be understood that the mere accident of being called to attend a Royal Personage should be the only way of attaining distinctions, highly valued and so freely conferred on lawyers, merchants, and others, but so seldom granted to Medical men, and almost never to those who follow a strictly scientific career.

The claims of Sir William Jenner must stand first in regard to the Prince, and would certainly do so in reference to his great talent and learning. He is already a baronet, and if the recovery of the Prince is to be marked in any such manner as has been hinted, it is but right to urge that the time has come to ask whether a baronetcy is to be the final honour ever bestowed on the Profession. To omit reward for his services and give a title to another attendant would be an injustice to him and to the Profession.

The *Times* has naturally alluded to the difficulties supposed to attach to an extension of the peerage. The question of wealth might not alone determine this. When other men have been raised to the peerage this difficulty has been overcome. The hereditary nature of these honours is quite another point, and raises the vexed question of life peerages.

As to Dr. Gull, no one would grudge him a baronetcy or knighthood. But let it be understood that Dr. Lowe equally deserves it, so far as attendance on the Prince goes.

It may also be fairly said that the usual attendants of the Prince seem to have been, by mere accident, prevented from doing what they would have done, as well as their more fortunate brethren, had circumstances have been somewhat different.

This shows, further, that this occasion should be seized to satisfy the Profession by promotion of a considerable number of leading practitioners, among which nearly all those who hold appointments to the Royal family might be numbered. Such an act, graceful in itself, would, we are sure, accord with the public feeling; while a single baronetcy would in no way be a worthy expression of Royal gratitude, or of public recognition of the value of the art of healing.

We speak the feeling of the Profession when we say that if Gull deserves a baronetcy, Jenner deserves a peerage; but we firmly believe that the full recognition of the claims of medicine—and of science, with which medicine is so intimately allied—would be received by those fortunate enough to be employed at Court, as well as by their less lucky brethren, in the best possible spirit.

The *Times* has suggested that our K.C.B. would perhaps be a good title to confer on medical men. The suggestion is an excellent one, and we should be glad to see it carried out. As a rule we do not want hereditary honours. Medical talent, or learning, is no more hereditary than are the qualities that have raised soldiers and lawyers to eminence. The distribution of a large number of orders not hereditary—would do something to remove the injustice under which the Profession has so long laboured; and we almost hope that it may be done.

Still, it is almost hoping against hope. This journal has again and again pointed out that men who have served their country well in the medical department of the Army and Navy, have been omitted from *Gazettes*, when the other services have been promoted in large numbers.

Only a few months ago we showed that Dr. Gordon, C.B., after enduring all the horrors of the siege of Paris—sent there by the Government—had not been promoted to the next rank in his order; while non-medical men had been gazetted in considerable numbers. This injustice still exists, although the matter excited attention in the House of Commons, and was left till the appearance of the report of that officer and the others engaged in similar service.

The Director-General, we doubt not, has reported on the matter; but the Government has, at present, done nothing. If the promotion from C.B. to the more dignified K.C.B. is so slow in the case of an army servant, who has served in several campaigns, can we hope that in civil life it will be so extended as to signalise worthily the gratitude of the Crown and of the people towards the most beneficent of the Professions.

If the *Times* should aid in the accomplishment of such a reform, we will gladly acknowledge that it has done good service.

Another physician of the highest eminence and position, and one, too, who has earned the thanks of us all as a medical reformer, is Dr. Burrows, the President of the College of Physicians. In honouring him and his office the Crown would honour us all. We should also be glad to see the President of the Royal College of Surgeons receive recognition—although, as is well known, we entirely differ from him in respect to his medical politics. Still, his scientific eminence and his position give him a claim.

The medical members of Parliament ought not to be passed over. The honourable Member for Colchester, Dr. Brewer, stands pre-eminent among these, and his public services at the Asylum Board, and in other onerous positions, ought long ago to have been recognised by a baronetcy.

We might add many other names—but what boots it? We fear there is little hope of that recognition of our Art which can alone satisfy public sentiment. Would that a *Gazette* with scores of illustrious medical names, might inaugurate a new era, and bring the most practical and beneficent Profession into accord with our other institutions. The Crown would be honoured by the act, and the public would applaud.

In one of those short paragraphs of the *Spectator*, which are so characteristic of that able journal, it is remarked, that to make medical men Privy Councillors would not affect their wives, who are, perhaps, most interested in these middle class decorations. The reluctancy to enlarge the Order of the Bath is scarcely comprehensible. Still, that too is met by the *Spectator* with a proposal to carry out an idea, once attributed to the late Prince Consort, and found a new order for scientific or intellectual service. "Why not the order of the Rose—the ancient emblem of science—as well of the Thistle?" says our contemporary. We echo the question—Why not?

It is certainly time for some move in honour of our Art, and though there can be no objection to its having a share in all historic honours, there would be little objection to the creation of a new distinction, provided it were put on a par with older orders in the matter of precedence. At any rate, it would be a beginning.

◆

THE ALCOHOLIC MANIFESTO.

If we are to believe the homœopaths, eclectics, and other genera of heterodox practitioners, the greatest opprobrium of allopathic or scientific medicine and its practitioners is their almost invincible conservatism. It is repeatedly thrown in our teeth that our teaching is so dogmatic and our practice so routine, that centuries revolve before the greatest and plainest truths of nature's laws are accepted and acted upon by us; and we are reminded of the scores of years and thousands of cases which passed by us before it was found out that our patients were being bled to death in accord with the doctrine of antiphlogistic remedy. Even now that all this is changed, even when the younger members of the profession are in headlong haste after new remedies and novel theories, it must be confessed that the mass of the profession and its leading minds exercise a weary deliberation before assuming facts or taking up a public position on them. In this view the manifesto, which we published the week before last, in which a contingent of the profession, socially and scientifically influential and numerically imposing, gave an utterance of warning to their brethern, was doubtless the most noteworthy medical document of the year 1871.

An examination of the names attached to the declaration gives an overwhelming importance to it. Many of the men who signed it possessed a knowledge and experience of the subject such as none but the confidential physician in extensive practice can have, and we cannot believe that men of such high-wrought caution and tender honour would have been induced to pledge themselves publicly to such an opinion, unless under the impulse of an urgent sense of duty.

We cannot, however, but feel deep regret, not only that the extent of private intemperance is so great as to justify and require such a declaration, but that it was necessary that the medical profession should be connected with it in so undesirable a phrase. It appears to us that the wording of the statement has conveyed an unnecessary and unjustified censure upon medical men. It may be true that private intemperance is a great and increasing evil—it may, even, be the fact that that misfortune has been caused by the over-riding by medical men of the Todd or stimulant method of treatment, but it is not for any body of men to condemn as "inconsiderate," the adoption of a given method of practice which, we are bound to presume, was employed with all proper caution and in perfect *bonâ fides*. Yet though we admit that the wording of the manifesto may convey an unjust imputation, we are satisfied that the abuse of stimulants in medical practice has received its death blow.

◆

SCOTLAND.

EDINBURGH.

The various classes in the University were re-opened on the 3rd inst., after the Christmas recess. It will be learned with regret that in consequence of failure of health, Prof. Bennett has been compelled to relinquish the duties of his Chair for the remainder of the Session. Although suffering for some time from indisposition, Dr. Bennett has, up till now, conducted his classes with his wonted energy, and, in addition, given a separate course of lectures to ladies. His professional friends, however, have declared that it is no longer possible for him to continue, and insist that he shall proceed to the South of Europe for the remainder of the winter. With consent of the Senators and University Court, Dr. McKendrick will deliver the remaining lectures of the course, and conduct the general work of the class.

> "That henceforward all registered students of medicine shall be admitted to the educational advantages of the Infirmary, without distinction of sex—all details of arrangement being, however, left to the discretion of the Managers."

The Annual meeting of contributors to the Royal Infirmary was held on the 2nd, and after a stormy discussion, terminated, it is considered, in the complete triumph of the party in favour of the admission of ladies. The first business of interest before the meeting was the election of managers. It was moved by the Rev. Dr. Nicolson, that no change of the Representatives should be made for the ensuing year, on the ground of the experience which these Representatives had acquired, being especially useful at the present time, as connected with important business affecting the efficiency of the present Infirmary, and the building of the new. The Lord Provost moved—"A list of gentlemen who were in favour of the ladies." This motion was seconded by Mr. Coventry, in a speech advocating the claims of the ladies for admission to the Infirmary, and denying that any special experience was required for conducting the business of the Infirmary. Mr. Edward Blyth, a nominee of both parties, said that he held very strong views indeed about the undesirability of changing the present representatives, and he wished distinctly to state that, in the event of the present managers being displaced for the purpose of carrying out an altogether subordinate question, he declined to go to the Infirmary as the nominee of the ladies. After some further discussion, the vote was taken, when the Lord Provost's motion was carried by a majority of nine. A poll was demanded, and the tellers were appointed to scrutinise the votes, and report to the adjourned meeting. Professor Masson was then proceeding to speak to his motion, when he was interrupted by Dr. Nicolson, who objected that no sufficient notice of motion had been given. Considerable confusion then took place, the Lord Provost (chairman) insisting on Mr. Masson going on to the exclusion of all objectors, and it was only on Sir Robert Christison expostulating with the Chairman that Mr. Auldjo Jamieson was heard to say that it was not competent at any public meeting to propose fundamental changes of rules of an institution like the Infirmary, without due notice. It was contrary to common sense, and on behalf of himself and others, he protested and took instruments. Professor Masson said he was willing to go on under protest. Mr. Jamieson then rose and left the hall, followed by Sir R. Christison, Mr. Blyth, and nearly all those who had voted with Dr. Nicolson. Being thus left to the freedom of their own wills, Prof. Masson and the Rev. Dr. Guthrie entertained a delighted and enthusiastic audience, who unanimously adopted the motion. The following is the resolution adopted by the University Court on the recent appeal laid before them.

> "Having considered the appeal of Professors Masson, Bennett, and Calderwood against the resolution of the Senatus of date 11th November last, representing to the University Court the propriety of rescinding their resolutions and regulations in reference to the admission of women to medical education in the University, without prejudice, however, to the rights and interests of those ladies who had already entered upon a course of study in pursuance thereof, and without prejudice to the right of Professors to give separate instructions to ladies in such classes as the University Court might from time to time think fit and approve; and having heard the appellants in support of the appeal, and Professors Muirhead, Turner, and Lister against the appeal: find it inexpedient at present to rescind the said resolutions and regulations, and therefore decline to give effect to the representation of the Senatus. The Court must not be understood as indicating by this deliverance any opinion as to the claim of women to proceed to graduation, or as to the power of the University to confer on women Degrees in the Faculty of Medicine."

◆

Notes on Current Topics.

The Conjoint Examining Board for Ireland.

The meetings of the Conference appointed by the various Irish Licensing Bodies to debate this subject have continued since our last issue. The proceedings are, of course, private, and the only information which has transpired is that the principle of the Duke of Richmond's amendment, which caused the death of last year's Medical Bill, has been urged upon the Conference by certain of the University representatives.

Our readers will recollect that the Medical Bill, as originally introduced in the House of Lords, provided that every candidate for the State qualification in Medicine and Surgery, whether he started from the Corporation or the University, should pass through exactly the same process, and that no special favour should be granted to the *alumni* of any educational body. This would have been manifestly just and fair. The Corporations asked for no protection, and they demanded that they should have perfect equality of competition with the Universities, but the influence of the University of London induced the Government to introduce the 18th Clause of the Bill, and to give to University students a complete exemption from the greater part of the examinational curriculum. This step changed the support of the Colleges into opposition, and was fatal to the Bill.

We earnestly hope that such a disturbing element will not be introduced into the negotiation. If the conjoint examination is not a free and unrestrained competition, it is nothing, and a special favour given to any body would not only create a strong and well-founded sense of injustice in the Licensing Bodies, but would prevent the settlement which, it is hoped, is now being arrived at, from being stable or satisfactory.

The Conjoint Board for England.

THE London Colleges of Physicians and Surgeons have submitted a scheme to Sir R. Palmer, the Hon. Mr. Denman, and Mr. Bevis, who are of opinion that it can be legally carried into effect. The other English bodies named in Schedule A of the Medical Act will co-operate, except the Society of Apothecaries, which considers that it cannot do so in accordance with its Act of Parliament. But Acts of Parliament may be modified or fall into disuse, and if the scheme prospers it may well be that the Society has had its day of licensing. The profession would not regard a diminution in the number of "medical authorities," even at the expense of a body which has certainly deserved well.

The object of the scheme is to establish a board of examiners for England, each corporation while retaining its powers to grant honorary distinctions, agreeing to abstain from the exercise of its independent authority to give admission to the Medical Register.

Our readers are well aware that we long ago pointed out that a little honest desire to serve the profession, and a conciliatory course was all necessary to enable all the authorities to come to an agreement. We have many times insisted on the feasibility of a simple as well as a more complete method, than that which has at last been accepted; but we readily welcome any plan that promises to prove a step in advance. There is indeed little time to lose if the several schemes are all to be submitted at once to the General Medical Council.

We hope that body will take them up in earnest, and so contribute something to a real reform.

But should the several schemes even yet fall through—and looking at the past who can say this is improbable, we trust the Council will act vigorously, and submit a more perfect plan to the Government.

Well would it be for the profession if Parliament would intervene with the offer to all recalcitrant bodies, of submission or disestablishment.

The Hampstead Inquiry.

THE Report of the Local Government Board has appeared, and has probably been read by all who were interested in the inquiry. We cannot but feel satisfied that it entirely confirms every statement made in the elaborate critical report we had the pleasure of submitting to our readers. Those criticisms have been everywhere received with the attention due to them, and to the very distinguished gentlemen who day by day watched the investigation on our behalf. Indeed, it is no idle boast that on this question, the MEDICAL PRESS AND CIRCULAR was the leader of public opinion—the inspirer of the most important articles of the daily and weekly press. Some of our contemporaries satisfied themselves with reprinting portions of the evidence, going on fruitless errands of inspection as to charges that related to long-past matters. All this could only be useless, and was a waste of paper and type.

We know that the careful, judicial review of the inquiry that appeared in the MEDICAL PRESS AND CIRCULAR was of real value, and those who wish to obtain a summing up of the whole by a master hand, must refer to that review. We record, therefore, with pleasure that the official report confirms all we have stated.

The London Institution.

A LECTURE was delivered at the London Institution, at four o'clock, on last Thursday, the 4th inst., by Mr. J. C. Brough, F.C.S., on "The Magic of the Mediums," being the third of a holiday course, consisting of four lectures on "The Philosophy of Magic." There was a very large attendance, the room being literally crammed from top to bottom, many people being obliged to stand. The lecture was well delivered, and was very interesting, exposing the deceptions of the so-called spiritualists, clairvoyants, &c. From what we have seen, we should say holiday courses are a very good experiment, scientifically and financially. The next and last lecture of the course, on "The Magic of the Laboratory," will be delivered to-morrow afternoon (Thursday, 12th) at four o'clock precisely. The lecturer will perform numerous experiments.

The Sewage Question.

THE important Special Reports on the Sewage question, that appeared in our columns last year, are being reprinted, with a quantity of additional matter. They will, we have no doubt, work an epoch in the discussions on this vital sanitary question. In no other publication can such a mass of trustworthy scientific evidence be obtained; for, although some of our contemporaries ventured to commence an opposition series of Reports, they were constrained to stop after the issue of their introductory sections. In truth, a more ignominious failure can scarcely be conceived than that which resulted from the attempt to compete with these reports. It was our good fortune to secure this valuable material for our subscribers. The sanitary department of the MEDICAL PRESS has achieved a position which it will be our constant desire to maintain; and however opinions may differ, we trust that our supply of this obvious want will secure us still larger support from the Profession.

The Pink Stocking Craze.

THE sensation evoked some time ago by the harrowing description by the *Lancet* of the gregarines, which were supposed to inhabit ladies' chignons, was varied shortly afterwards by a learned disquisition and agonising description of the miseries of women who worked at sewing machines, and lastly, the public was horrified by a denunciation of pink stockings from the same journal. The two former alarms were proved to be quite foundationless as soon as competent microscopists and reliable statitiscians came to deal with them, and, now, the last wolf-cry has been shown to have no more basis than its predecessors.

On the 27th of December, M. Beclard read a communication to the Academy of Medicine of Paris, on the action of coralline on men and animals, of which paper the following is the conclusion:—Pure coralline, under the different forms in which it is ordinarily used, is a completely harmless substance. This decision is arrived at by the uniform results of the experiments of Dr. Laudrin and M. Tabourin. The art of dying by means of these pigments may be carried on with perfect safety if the fixing agents have no poisonous property in themselves.

The Reparative Efforts of Nature after Gastrotomy.

The *Union Medical* exhumes from a medical periodical of 1761, an account of an autopsy made on the body of a famous glutton, a tripe seller, on whom it had been necessary, twenty-years before, to practise gastrotomy and remove eight inches of the cæcum and colon, which were gangrened. When on the autopry the intestine had been tied and inflated, it was discovered that Nature, so fertile and admirable in its methods, had substituted for the intestine which had been cut away, a prolongation of the peritoneum, and that structure served instead of an intestinal canal.

Poisonous Effects of Zinc Utensils.

The *Union Medical* calls attention to a new source of danger, caused by the substitution of zinc for tin in the manufacture of pots and pans by travelling tinmen. Zinc sheet can be had at seventy centimes the kilogramme, while tin costs three or four francs, so that it is often substituted in the making of kitchen utensils. The fraud cannot be detected by the eye, but a little vinegar boiled in the vessel will immediately corrode the surface and, if done in the process of cookery, will give rise to symptoms of poison.

Small-pox in Belfast.

Forty-one small-pox patients were admitted into the Belfast Union Hospital during the past week, and the total number remaining on Tuesday showed an increase of nine over that of the previous week. Dr. Reid reported that in his belief the accommodation for small-pox patients would in a few days be insufficient, owing to the steady increase in the admissions, and requested the removal of all non-contagious patients to the workhouse, reserving the hospital for small-pox and fever patients. Dr. Johnson appeared before the Board, and stated that if this arrangement were made, he would be unable, single-handed, to attend to all the patients that would be handed to him, and suggested the appointment of an additional visiting medical officer to assist him. After considerable discussion the Board elected Dr. Mulholland. That gentleman is at present a Poor-law Guardian; but if the Commissioners approve the vote of the Board he will resign, in order that he may be able to accept the appointment. It was arranged that should the Commissioners object, Dr. Hill will be appointed.

Disinfectants.

M. Langlois summarises some observations on the different modes of action of various disinfectants submitted to the *Conseil de Sante* of the French army. He notices the circumstance that various chemical agents so designated, act differently upon different putrid emanations with which they are brought in contact; and, moreover, that such emanations have not all the same origin, although they are for the most part produced by the spontaneous decomposition of animal *debris*, or nitrogenous organic matters. During that decomposition, they disseminate through the air gas more or less infected, formed in great part of ammonia, sulphuretted and phosphuretted hydrogen, to which is added water holding in suspension organic particles themselves in process of decomposition as well as living organic corpuscles, germs, spores, &c., these being the products which constitute miasmatic infection, the influence of which is so prejudicial to the public health. The means most frequently used to purify and disinfect air thus tainted are chlorine, hypochlorites, and phenic (carbolic) acid, in variable quantities according to whether the places to which they are applied are inhabited or not. Chlorine, however produced, destroys the odour of gases by forming with their elements, new and inodorous combinations; yet, when present only in small quantities in the respirable air, it is doubtful if it be capable of destroying all the miasms which, under the form of microscopic corpuscles exist in it. If chlorine alone should seem to be insufficient for the purpose, the lighter vapour of phenic acid appears to act rapidly and powerfully in destroying these living principles, although it is without effect upon the fœtid gases. Hence, it results that, order to disinfect and purify a mephitic and miasmatic atmosphere, it is necessary to employ simultaneously the vapour of chlorine and of phenic acid. Chlorine disengaged in large quantities in a confined atmosphere, decomposes not only the mephitic gases, but oxidises and *burns* the organic matters, which are present with them, its mode of action being the withdrawal of their hydrogen, by which oxygen being set free, its oxidising power while in the nascent state is brought into action.

A similar action is obtained by the use of nitrous gases, these by withdrawing the oxygen passing into the state of *hypo-nitrous* which, in its turn undergoes a decomposition in contact with the water contained in the atmosphere, into which it is disengaged.

Phenic acid acts by checking or arresting decomposition of animal matters in the same way, according to M. Dumas, as tannin. Smoke, soot, tar, and creosote from containing this acid in greater or smaller quantity, act in a similar manner to it. Certain of the metallic salts are also used for the destruction of mephitic gases, and producing with their constituents inodorous compounds, among others, the salts of iron and zinc. These salts moreover prevent alteration in organic matters. Charcoal and certain porous earths absorb offensive gases, and delay putrid fermentation in substances susceptible of that mode of destruction.

For the purpose of volatilising phenic acid, the following combination is recommended, namely: — Crystallised phenic acid, 500 grammes; alcohol of 85°, 500 grammes; water, 5 kilogrammes. The impure acid may be employed when procurable on account of its relative cheapness.

The Children of our Soldiers in India.

A very important article in the *Indian Medical Gazette* for September has attracted our attention. It shows that the health and the lives of the children of European soldiers in India are being sacrificed in a manner that should attract the attention of the Government, and which public opinion will not fail to take note of. In Bengal alone, in 1869, no less than 826 of these children died out of 5,688. This is nearly double the mortality of twenty years ago.

Why? The writer of the article in the *Gazette* gives us some important information. He tells us that taking the average of the six years, 1864-9, and speaking roundly, the children of European soldiers—the very great majority living in the plains, and in many instances ill-fed—*have in each year been all but decimated.*

In contrast with this we take the Military Asylums at Murree—containing soldiers' children of precisely similar parentage to those who while with their parents and regiments die with such fearful rapidity—the children in the Murree Lawrence Asylum live in an excellent climate, 6,500 feet above the level of the sea, and are provided with a very liberal diet—with what results, as regards health, let the following figures show:—Since the Asylum was opened in 1861, it has afforded shelter to an average annual number of 85 children of both sexes, and at ages varying between 5 and 14 years. These children are in rude health, only 3 out of their number being constantly sick, and in 10 years they have lost only 6 by death—one, a case of accidental poisoning, another due to cholera, two more or less attributable to disease previously contracted at Peshawur, the remaining two being caused by lung affections. Again taking the Mount Aboo Lawrence Asylum, in which, as Dr. Moore tells us, during the "five years ending 1870 only one death, and that from epilepsy, occurred among an average number of 50 children" of European soldiers. Lastly, take the Lorretto Convent at Darjeeling, containing an approximate annual average of 70 children—of somewhat a better class than those in the two before-mentioned institutions. Here only one death occurred in twenty years.

But a good climate alone, although it very sensibly diminishes the death-rate, is not capable—in the absence of suitable nutriment—of producing all the good results desirable. In 1868, 513 children were located with their regiments and at depôts in the hills, the death rate amongst them being 68·2 per 1,000 per annum, against 88·9 per 1,000 amongst the 4,442 children during that year resident in the plains. In 1869, 564 children in the hills exhibit a death rate of 89·8 per 1,000, while the mortality amongst those in the plains mounted up to 149·0 per 1,000. Taking the difference between the loss of life during these two years (the only ones the Sanitary Commissioner's published statistics enable us to deal with)—in the hills, and in the plains, we find that it amounts to 39·9 per 1,000 in favour of the hills. That is to say—although the mortality in the hills was very much greater than it should be—the removal of a certain number of these little children to a good climate, saved in one year, twenty lives out of every 500 so removed. This saving of life is, we take it, wholly due to change of climate, as soldiers' children, while with their parents are equally well (or ill) fed, housed, and cared for in the plains as they are in the hills. But the mortality amongst soldiers' children even in the hills is still deplorably great.

The Asylum at Murree, in 1868 and 1869, contained 93 and 118 children, amongst whom not one death occurred in the two years. In the same years and in the same station 200 children of soldiers living with their parents at the depôt and in the family camp, had 37 deaths amongst them, although no epidemic prevailed. At the Loretto Convent, Darjeeling, in the three years 1866 to 1868 one child out of 70, or over, died. In the same time and place 10 deaths occurred among 50 children of the 58th Regiment.

It is the opinion of the careful writer already quoted, he is evidently thoroughly conversant with the matter, that the great mortality is due to defective food through the pay of married soldiers not being enough to enable them to provide for their families. Furthermore, he tells us that in 1869 we had in our European Bengal Army 2,693 married privates. Of these about 2,500 were, with their families, sweltering in the plains, and in this year of grace about the same number is in the same condition. Should the extension of our communications lead to the location of all our European soldiery (except the few absolutely required to garrison strongholds in the plains) on the hills in India, the married soldiers will be *then* also removed from the plains. But, in the meantime, why keep 2,500 married privates in the plains? Their children are being all but decimated year after year. Simple change to a hill climate would alone be the means of saving probably 40 out of every 1,000 lives annually. The number of sites at our disposal, and the facility and cheapness with which huts, admirably adapted for the location of our soldiers' families, can be constructed in the hills, leaves little excuse for delay.

The writer offers the following recommendations:

> "When once placed in a hill cantonment, leave the married soldier as much as possible undisturbed. If a regiment be moved from, for instance, Agra to Sealkote, that is not, or ought not to be, a valid reason for the removal of its families from (say) Raneekhet to Murree. Although carriage be provided free of charge, yet—as is well known to those acquainted with married soldiers—a move of any kind involves them in pecuniary difficulties which they can ill afford to meet. Besides, permanent location in the hills would probably tend to develope a taste for agricultural and other profitable pursuits on the part of the soldier. But even with these advantages we are still of opinion that the Government allowance for at all events privates' children should be raised. An addition of two rupees a month for each child would, we are convinced, effect a very great change for the better, and this increase would not cost more than about £6,000 a year in the whole of Bengal. Putting higher considerations out of the question, we think this money would be profitably spent. These married soldiers' hill cantonments would simply be healthy nurseries, which, *under proper supervision and management*, would afford us yearly a batch of well-trained, hardy recruits for our Indian Army on the spot— thus saving the great expense of importing an equivalent number of frequently undesirable recruits from England. The Indian Government feeding, clothing and educating these children liberally, should have a claim upon their services when they arrive at manhood, and might thus supply itself with thoroughly-trained material for the manufacture of that every-day-more-difficult-to-be-obtained commodity—good non-commisioned officers."

The Vacant Surgical Baronetcy in Ireland.

In another place we have commented on the proposal to confer upon the medical attendants of His Royal Highness the Prince of Wales, those honours which are the only recognition, however inadequate, which it is in the power of the Sovereign to confer. We return to the subject in order that we may point out the anomalous position which the surgical profession in Ireland occupies in respect to the distinctions which are its due. While medical Baronetcies have been from time to time distributed in England and Scotland with no scant liberality, the profession in Ireland has not only not been honoured by any fresh decoration, but the sparse dignities which it formerly possessed have been allowed to lapse. True, Sir Dominic Corrigan has received upon worthy shoulders the baronial robes of Sir Henry Marsh, but we ask, what has become of the twin surgical baronetcy, to which Sir Philip Crampton did honour for so many years. While there is no lack of surgeons in Ireland who might do credit to the exercise of Her Majesty's prerogative, the baronetcy has year after year remained untenanted. It is not for us to select a fitting recipient further than to say that we trust the office will remain unfilled sooner than it shall be made the reward of religionism or political services. We have long since claimed for Robert Adams the first position on the record of worthy successors of Sir Philip Crampton. If at any time Her Majesty shall see fit to confer upon him such a decoration as he can accept, every surgeon in Ireland will be ready to stand aside and accept the distinction as an honour to himself and his profession. Failing Mr. Adams's candidature, we do not hesitate to name Mr. Porter, the Queen's surgeon, as a member of our profession, to whom no man need grudge so well deserved an honour. We utter in no spirit of envy the complaint that Irish surgery has been undeservedly passed over by the adviser of Her Majesty, and we indulge the hope that the professional distinction which has been so long absent from Ireland will be restored to it in the person of a surgeon who will have achieved his decoration not by political peculiarities, but by honest scientific surgery.

The Surgeoncy to the Meath Hospital, Dublin.

The election of a Surgeon to the Meath Hospital, Dublin, in the room of the late Dr. Mayne, took place on Saturday last. As between the gentlemen whose names were current in the profession, or other candidates of equal pretensions, it is not our business to speculate, and whatever opinion we might have held as to the fitness of a candidate, we should not think it right to follow the *Irish Times* in the effort to impose our own favourite, if we had one, upon the medical electors. The adoption of such a course by a public journal, strikes us as being uncalled for, indecent, and unfair, and doubly so when a political aroma attaches to the recommendation. If the electors to the Meath Surgeoncy should have made a bad selection, they are open to criticism, but until they have done so no newspaper possesses a right to dictate to them or to assume that a dozen candidates of superior qualification will not present themselves for election.

The choice of medical officers to the Meath Hospital is vested by a special Act of Parliament, in the medical board. In every other county infirmary the governors choose the officers, but many years ago the medical staff of the Meath, in return for their surrender of any claim for emolument, were given the power of electing their successors. As to the choice of the electors in this instance, we confine ourselves to the statement that they have selected Mr. Lambert H. Ormsby as the successor of Dr. Mayne.

Mr. Ormsby obtained the Licentiate of the Royal College of Surgeons, and the King's and Queen's College of Physicians in the year 1869, and has been a demonstrator of anatomy in the school of the college for the last four months.

Army Medical Department.

Staff Surg. Johnson has assumed medical charge of the General Hospital, Dublin. *vice* Staff Surg.-Major Dr. Bawtree, whose retirement on half-pay is shortly expected to appear in the *Gazette*. Staff Assist.-Surg. Waters has arrived at Londonderry for duty from Tuam.

Fever.

Dr. Herbert Davies, Senior Physician to the London Hospital, will, this evening, read a paper at the Hunterian Society, on cases of continued fever treated by the external application of cold. Whatever this accomplished physician puts forward is sure of the earnest attention of his brethren.

Dr. Tilbury Fox has been nominated by the President a member of the Leprosy Committee of the Royal College of Physicians.

The next competitive examination for the admission of Assistant-Surgeons into the Royal Navy, will take place at the University of London, on the 12th of February.

By the latest mails from India we learn that there are now but a few isolated cases of cholera in different parts, and that the general health of the country is excellent,

Enteric fever and small-pox are very prevalent in Woolwich, the sanitary condition of the town is very wretched, and contributes very materially to the spread of these diseases.

In consequence of the alarming epidemic of small-pox at Wolverhampton, the Government has sent Dr. Stallard to ascertain the cause, and to confer with the authorities of the town, with a view to stamping out the disease.

The Lettsomian Lectures will be delivered by Dr. Haberson, F.R.C.P., before the Medical Society of London, 32a, George street, Hanover square, W., 1872, on Monday evenings, January 8th, 22nd, and February 5th, at 8.30 p.m, "On the Pathology and Treatment of some Diseases of the Liver."

Next Friday, at the Clinical Society, Dr. Ogle will draw attention to the temperature in nervous diseases with special reference to tetanus. Mr. Carter will relate a case of paralysis of the external rectus, and Mr. Cooper Forster a case of popliteal aneurism.

It is reported that the authorities of the Brompton Consumption Hospital will shortly become possessed of the enormous bequest of £110,000, by the will of an eccentric old lady, named Reid, who died in the south of London under peculiar circumstances some few weeks since. We believe the relatives of the deceased intend to contest the validity of the will.

The Australian Chief Secretary has intimated to the Medical Board, that it will not be possible for him to introduce the amended Medical Bill into parliament this session, but he has requested to be supplied with such particular information, as will enable him to point out in what respect the proposed act differs from the old one; so that he may bring it on at an early stage of the next session. The Pharmaceutical Bill, it is to be presumed, will, in like manner, have to wait its turn.

It is stated by one of the local papers of South London, that the Metropolitan Board of Works, with a view to ascertaining whether there is any connection between typhoid fever and sewage emanations, have requested all the metropolitan vestries to send in returns of the number of men and boys employed in flushing and other sewer work, and the number of any that may have been attacked with typhoid fever.

We have several times drawn attention to the use of gymnastics in the treatment of disease and in the preservation of health. In the course of a tour of inspection made to the London gymnasiums we were agreeably surprised to find the children of several of our professional brethren, among them the son of Dr. Lionel Beale, taking a course of gymnastics with M. Bertrand, the able professor of the National Orthopædic Hospital. The class we saw was one held for the pupils of Miss Woodman. We congratulate that lady on the good sense displayed in thus securing for her pupils the best possible physical training, and only wish that all having the care of children would follow her judicious example. It is quite certain that mental progress is best secured by whatever promotes the health of the body.

◆

THE HAMPSTEAD SMALL-POX HOSPITAL AND METROPOLITAN ASYLUMS BOARD.

On Saturday, at a crowded meeting of the Metropolitan Asylums Board, Dr. Brewer, M.P., the Chairman, presided.

The Report of the Committee of Management of the Hampstead Hospital was presented, which, after giving the statistics of that establishment, said, in reference to the recent inquiry, that the Committee would have been gratified if the Local Government Board had more specially recognised the manner in which the staff of the hospital performed their duties under unprecedented difficulties, and during a long and severe strain upon their powers. The Committee could not but feel that the long and searching inquiry into the management of the hospital had abundantly proved that the grateful thanks of the Committee were due to the medical superintendent, sisters and nurses for their untiring labours, watchfulness and skill in the treatment and nursing of the sick entrusted to their care during the recent severe epidemic of small-pox. The Committee had most carefully considered every point brought out in the inquiry which showed any defects in their arrangements. The majority of the suggestions of the Local Government Board had been already adopted, and the others would be maturely considered. The law costs of the inquiry were £771 18s. 7d. The Committee begged to annex for the information of the Managers an extract from a recent report of the medical officers of Hampstead. It stated that the census taken on Sunday last gave a total population of 32,271. After excluding such new population as has been brought into the parish through the Small-pox Hospital, St. Peter's Home, and the North London Consumption Hospital, the death-rate of Hampstead has very slightly exceeded 14 per 1,000. It was evident, therefore, that in spite of the existence of the small-pox Hospital, Hampstead has not ceased to stand at the head of suburban districts in respect to health.

Mr. Wyatt, J.P., moved the adoption of the Report, which was seconded, and carried unanimously.

Sir James Hamilton, Bart., then moved the following resolution :—"That this Board avails itself of the earliest opportunity of expressing its satisfaction at the result of the lengthened inquiry instituted by the Local Government Board, into the management of the Small-pox Hospital at Hampstead, and at the same time tenders to the Chairman (Mr. Wyatt) and the members of the Committee to whom the direction and management of this hospital were delegated, the assurance of its entire confidence in them, and the expression of the Board's best thanks for their active and energetic services during the recent epidemic of small-pox, and for the zeal and assiduity with which, regardless of personal danger, they discharged the very painful and onerous duties that devolved upon them."

Dr. Cortis seconded the resolution, and referred to the avidity with which the public, acted upon by certain portions of the press, received and believed the sensational tales put forward by those who had made the charge against the management of the Hampstead Hospital. Whilst all the statements which outwardly had the semblance of reflection upon the management of the hospital were swallowed, as disclosing the most horrible ill-treatment of the patients, the evidence given in exculpation was scarcely heeded, indeed, hardly read at all by prejudiced minds (hear, hear). Happily, however, public opinion was not the only tribunal to which the managers of the Hampstead Hospital had to appeal for judgment (hear, hear). There were the thoughtful and unbiassed, minds of the gentlemen who conducted the inquiry, and the public and responsible body to whom they had made their report (hear, hear). So far from being permitted to suffer the stain of the slightest obloquy the Chairman and gentlemen of the Hampstead Hospital Committee deserved the thanks of the entire country (applause).

The resolution was put and carried unanimously, amidst renewed applause.

After a few remarks from Mr. Wyatt, J.P.,

Sir James Hamilton moved a resolution expressive of the high esteem and unabated confidence of the managers in the medical superintendent, and head and other nurses of the Hampstead Hospital, throughout the prevalence of the late epidemic, and congratulated them on the scatheless manner in which they had passed through the ordeal of the late inquiry, notwithstanding the imputations attempted to be cast upon them.

Mr. Galsworthy seconded the motion, which was also carried unanimously, amidst applause.

◆

THE PREVENTION OF VENEREAL AND ITS POLITICAL DIFFICULTIES.

(Special Report, prepared expressly for the Medical Press.)

(*Continued from Page* 17).

The second part as to medical evidence of the inutility of the Act is thus considered :—

"The medical evidence which was submitted on the part of the opponents of the Acts, dwelt chiefly on the admitted difficulty of distinguishing the contagious from the non-contagious discharges to which females, and especially prostitutes are liable. No new facts were adduced in this evidence, nor did it satisfy the medical members of the Commission either that there is any better, or, indeed, any other, method of detecting venereal disease in the female than that described."

The Commissioners having, therefore, so far proved the efficiency of restraint and legislative action, have the option of three courses,—

1. To continue the Acts as at present in force.
2. To modify them.
3. To annul or do away with them altogether.

The general recommendation resolves itself into—

a. The abolition of the periodical examinations.

b. That every common prostitute found to be diseased after an examination by a medical officer upon a voluntary submission, or upon a magistrate's order shall be detained in a certified hospital until she is discharged by a magistrate's order, or by the authorities of such hospital; provided that such detention shall in no case exceed the period of three months.

There are other measures as to minor details, such as greater extension of the modified Act, offences against the person, consent at a tender age, beer-house irregularities,

&c.; but the gist consists in the modification of the two clauses first referred to.

The entrusting of such a power to the citation or discretion of the police might, it is said, be, at the least, subject to doubt, and might give them a dangerous power. The detention of women who would voluntarily present themselves for hospital relief would, on the other hand, largely defeat the very object in view: many of them would not enter hospital at all, unless altogether incapacitated by pain or debility. Such patients specially abhor restraint; as stated in the Report, "we are assured, however, that few women would enter on such a condition."

"We were informed that under the voluntary system, as it was called (to distinguish it from the compulsory enactments of 1866), many of the women would not come to the hospital, and if they came would not stay to be cured. The arrival of a regiment or a ship would empty the Lock wards. One of the hospital surgeons stated that 25 per cent. of the women went away before they were cured. The difficulty of detaining the women under the voluntary system is no doubt considerable."

Now, this is exactly the recommendation which the voluntary system presents to these patients; they *can* seek hospital relief when actually diseased, or when debilitated, yet leave when they please.

Seven of the Commissioners are, however, directly opposed to any such modification; and hold that the "Act of 1866-69, insisting on periodical examination, has produced physical results with which the Act of 1864—giving power to the police to cite a woman whom they have cause to believe diseased—cannot at all compare."

The Committee arrive at the conclusion that "although periodical examination is the most effectual mode of dealing with venereal disease, it would be difficult, if not practically impossible, to make the system general, even if on other grounds it were desirable." Yet, it would seem that even on the limited scale, in which the Act has been applied, a *great* diminution of the disease has been effected amongst the military and the naval, and we must conclude also amongst the civil, population in the vicinity—saving thus the infection of numbers of healthy men, wives, and children; and, therefore, that already an amount of good has been done, which will have its fruit in certain favoured localities; and as rural districts are pretty free from disease, were the Acts enforced more largely, especially in seaports, military stations, and populous towns, such an incalculable amount of good could be done that the disease would then diminish, and also assume what is found to happen in protected districts—*a milder type.* With regard to the latter question, it is to be regretted, that more attention has not been directed to it, the subject is one of great importance with reference to the permanent infection of the system. Whatever difficulties may be found in applying the Act largely over the Kingdom, it is now known that, wherever it is applied, an immediate and appreciable advantage has been gained. Its being inconvenient to wield so gigantic a machinery as would be required for universal application, should hardly, we think, be used as an argument against its application where it has proved practicable and most wanted, as in large towns and military stations.

The next proposition necessarily entertained is that of a modification of the controlling power—"That a woman who would voluntarily enter hospital, or if cited by the police as suspected of disease, should be detained even up to three months duration."

We rather apprehend that the detention in hospital of any who would so voluntarily enter, would act as a very powerful deterrent, and increase even the present difficulty, and that any interference of the kind will tend to defeat the end which it is desired to obtain. Better far, we believe (if the direct grappling with the evil, even so far as to check its progress by the wider application of the present compulsory Act be not thought desirable and not be practicable), leave things as they are—for instance, in this city, endeavour to induce the early seeking of admission by such patients, and their remaining under treatment till thoroughly cured; by affording them attractions in the way of hospital comforts, which will contrast with their condition outside, both as to food and lodging. Instead of tying down the management of such institutions within narrow limits, Government should supply them with no niggard hand—which in the end would be economy, as the disease would be alleviated though not, perhaps, in the marked degree testified before the Commission.

Foreign Medical Literature.

ON THE PHYSIOLOGICAL ACTION OF CRYSTALLISED ACONITINE.

(A Note of MM. Greliant and Duquesnel presented to the Acadèmie des Sciences, by M. Claude Bernard.)

(Translated for The Medical Press and Circular.)

In order to study the physiological action of crystallised aconitine we have first prepared a solution in water holding one milligramme of liquid solution to the thousandth part per cubic centimetre of water, then we have made on a frog the following series of experiments:—

1st experiment.—Under the skin of the back of a frog, was injected, by means of a syringe of Pravas, 1-20th of a milligramme of aconitine. At first the animal was agitated, the head bent down on the thorax; thirty minutes after the injection of this feeble dose of poison, the sciatic nerve being uncovered, had completely lost its motor power, whilst the muscles of the leg contracted as soon as they were excited by inducted currents. The thorax on being opened showed that the heart continued to beat regularly.

2nd Experiment.—On a frog the gastrocnimius muscles were detached, together with the sciatic nerves left adhering to the muscles. In a watch-glass the muscle is plunged in a solution of aconitine holding only 1-5th of a milligramme per cubic centimetre, the nerve is suspended without. In a second watch-glass the sciatic nerve is immersed in the same solution leaving the muscle without. The two preparations were covered with a damp cover. At the end of a certain time, the nerve of the first preparation had completely lost its excitability, whilst the nerve of the second made the muscle contract immediately it was excited. Thus, aconitine destroyed the motor faculty of the nerve by acting on its peripheric terminations.

3rd Experiment.—Before poisoning the animal the circulation was stopped in one of the posterior members, all the motor nerves which received poisoned blood lost their physiological property, whilst the nerves of the preserved limb remained perfectly excitable. It was proved that the animal remained sensible, whilst the motor nerves permitted the production of reflexive movements.

These experiments, made according to the method instituted by M. Claude Bernard in the study of curare, seemed to establish that, in small doses, the physiological properties of aconitine are analogous to those of curarine.

It is thus that aconitine destroys at first the motor power of the nerves.

In fine, we have made another experiment which at first embarrassed us. We injected in a frog a dose of one milligramme, that is to say, a dose twenty times stronger than that which served for our first experiment, our astonishment was great at seeing that the animal preserved a very long time the excitability of its motor nerves, and that it executed always spontaneous or convulsive movements. But in examining the thorax, then in opening it, we recognised that the ventricle of the heart had completely stopped and the auricles alone feebly contracted. The idea then struck us that the poison administered thus in a strong dose could perhaps primitively arrest the heart, which would also result in the arrest of the absorption.

The experiment completely justified this hypothesis. A frog was disposed under the microscope, for the examination of the circulation of the interdigital membrane ; an injection was made under the skin of one milligramme of aconitine ; a minute and a half after, the circulation showed itself considerably slackened in the arteries ; after three minutes, it had quite stopped. The thorax was opened, the ventricle of the heart was immovable. The nerves of the brachial plexus were found excitable, but a little less than the lumbary nerves, which had almost preserved their normal motor power. The heart being stopped, the poisoning could no longer take place except by imbibition as in the second experiment.

In mammals, the toxic phenomena produced by aconitine show themselves very rapidly and are much less easy to analyse ; nevertheless, we have injected in a rabbit one milligramme of aconite, then we have maintained artificial respiration, and at the end of half an hour the sciatic nerve no longer determined contractions in the muscles, which had nevertheless preserved their contractibility.

The physiological experiments that we have just exhibited have been performed in the physiological laboratory of the Museum of Natural History placed under the direction of M. Claude Bernard.

Letters to the Editor.—We are unfortunately compelled, for want of space, to hold over the following correspondence :—

"The Arts of Secret Poisoning." By Vindex.

"The Origin of the Circulation of the Blood." By Dr. McKeogh.

"Corrected Nomenclature." By Philologus Orthodoxus.

"Twin Births." By Dr. R. Sheil.

The Medical Press.—In addition to the ordinary circulation of the Journal, the number for this week (January 10th) has been forwarded to every physician and surgeon whose address is known in and around London. Should any gentleman read this notice who, by accident has not received his copy, it will be sent post free on application to the publisher.

Editor of The American Chemist.—Our Exchange List is quite full, we regret we cannot add your Journal to it.

Dr. Nottingham, Liverpool.—Your supposition is perfectly correct.

E. T. L.—Next Wednesday.

Several Reviews: letters, &c., are unavoidably postponed ; also some original communications, of which the following are in type :—

Mr. Henry Lee's second Clinical Lecture.

Pennefather, "On the Sense of Hearing."

Mr. Critchett's

Dr. Morgan.

Chapman, "On Uterine Neuralgia."

MEDICAL CLUB. Established 1866.—The Clubhouse overlooks Trafalgar square, "*the finest site in Europe,*" open to Professional Men and Medical Officers of the Army and Navy.

Several bedrooms are reserved in the house for the use of Members.

AFTER MARCH 31ST, 1872, THE ENTRANCE FEE will be raised to Fifteen Guineas, and the Annual Subscription to Six Guineas.

UNTIL MARCH 31ST, THE ENTRANCE FEE will be Ten Guineas, Annual Subscription Five Guineas. Members abroad One Guinea.

APPLICATIONS and REMITTANCES to be forwarded to Dr. Lory Marsh, Honorary Secretary and Treasurer, 9 Spring gardens, Charing cross, S.W.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.

FIRST or PRIMARY PROFESSIONAL EXAMINATION for the LICENCE. The next EXAMINATION will COMMENCE on MONDAY, FEBRUARY 5TH. Students are admitted to this Examination after the termination of the Second Winter Session of Professional Study at a recognised Medical School.

SECOND OR PASS EXAMINATION FOR THE LICENCE.

The next EXAMINATION will COMMENCE on MONDAY, FEBRUARY 12TH. Gentlemen who have completed four years of Professional Study according to the College Regulations are eligible for admission to his Examination.

Registered Medical Practitioners, qualified before January, 1861, are admitted to Examination under Special By-laws.

Candidates are required to give fourteen days' notice in writing to the Registrar of the College, with whom all Certificates and Testimonials required by the By-laws are to be left at the same time.

Pall Mall East, 1872. H. A. PITMAN, M.D., Registrar.

ST. THOMAS'S HOSPITAL, ALBERT EMBANKMENT, WESTMINSTER BRIDGE, S.E.—The Surgical Registrarship is now vacant. Any gentleman wishing to become a candidate for the appointment, is requested to send in his application (stating all qualifications) to R. G. WHITFIELD, Medical Secretary, on or before Thursday next, the 11th of January.

WEST RIDING LUNATIC ASYLUM.—WANTED, a CLINICAL ASSISTANT, who will be required to take notes of cases, and aid the Medical Officers generally in the discharge of their duties, and who will receive board and instruction in mental and nervous diseases in return for his services. As the asylum accommodates 1,500 patients, the opportunities for study and observation are very great. A gentleman possessing a qualification will be preferred.

Applications, with testimonials as to moral character, to be forwarded to me on or before the 10th inst.

J. CRIGHTON BROWNE, M.D.
West Riding Asylum, Wakefield, Medical Director.
January 4th, 1872.

SLIGO UNION.

SLIGO DISPENSARY.

AN APOTHECARY WANTED.—A Vacancy of APOTHECARY to the Sligo Dispensary having been created by the voluntary resignation of Dr. Loughead, the Dispensary Committee will proceed to elect a qualified Apothecary on Friday, 26th January, 1872, at a Salary of £75 per annum.

Candidates are requested to forward copies of testimonials, together with a statement of age, which must not exceed forty years, to the Hon. Secretary on or before the 19th January, 1872. Personal attendance will be required on the day of election.

DANIEL MACGILL, Hon. Secretary.
Sligo, 5th January, 1872.

PUBLIC SCHOOL EDUCATION IN IRELAND.

COLLEGE OF ST. COLUMBA, COUNTY DUBLIN.

VISITOR: THE LORD PRIMATE.

The College is intended for the Education of the Sons of the Nobility, Clergy, and Gentry, from the age of nine years and upwards. The course of instruction is similar to that of the great Public Schools in England, in which Classical Studies are made the chief foundation. Particular attention is also paid to Mathematics and English. French, German, Drawing, and Vocal Music are also included.

Boys are prepared for the Universities of Dublin, Oxford, and Cambridge; and to a considerable extent for the Military and Civil Service.

Terms—*Sixty Guineas*, inclusive.

There are Two Exhibitions attached to the School, tenable in the University of Dublin, worth £20 to £30 a year.

Applications should be made to the Rev. the WARDEN.

The Christmas Vacation ends on January 25th.

GENERAL HOSPITAL AND DISPENSARY FOR SICK CHILDREN, 16 BRIDGE STREET, MANCHESTER.

THE OFFICE of RESIDENT MEDICAL OFFICER to the above-named Institution will be vacant on February 10th. The salary of the resident medical officer is £100 per annum, residence and board in the Hospital. Candidates must have their names on the General Medical Register, and must be unmarried. Applications and testimonials to be sent to the Hospital on or before January 23rd.

NOTICE OF EXAMINATION FOR ENTRY OF ASSISTANT SURGEONS IN THE ROYAL NAVY.

NOTICE IS HEREBY GIVEN THAT A COMPETITIVE EXAMINATION for the admission of Assistant Surgeons into the Royal Navy, will take place at the University of London, Burlington Gardens, on Monday, 12th February, 1872, and following days, at 10 o'clock.

Candidates must present themselves at this Department on Friday, 9th February, 1872, bringing with them the various Certificates of Qualifications specified in the Regulations of the 24th June, 1871, when, should they be found in all respects eligible, they will be permitted to appear for Examination.

A. ARMSTRONG, *Director-General.*

ADMIRALTY, SOMERSET HOUSE,
Jan. 3, 1872.

DISTRICT MEDICAL OFFICER.—ST. PANCRAS, MIDDLESEX. The Guardians of the poor of this Parish will, on Thursday the 18th January, appoint a Medical Officer for No. 7 District. Salary £100 per annum. The Medical Officer is required to attend at the Dispensary at Compton place, or elsewhere, as may from time to time be determined by the Guardians for one hour at the least daily (Sundays excepted). Drugs and medicines are provided by the Guardians, and a Dispenser is appointed for the Dispensary. Candidates must possess the qualifications prescribed by the Local Government Board. The Officer appointed will be required to reside within the district, and otherwise to conform to the orders of the Local Government Board.

Applications (which must be made on forms provided for the purpose, to be obtained at this office), accompanied by diplomas and other evidences of qualifications, must be sent to me not later than 2 p.m. on Monday the 15th inst. Candidates are expected to be in attendance at the Vestry Hall at 4 o'clock p.m. on the day of election, but no travelling or other expenses will be allowed. Persons writing for a form of application must send a stamped directed envelope.

By order, DANIEL FILDEW,
Clerk to the Guardians.
Clerk's Offices, Vestry Hall, King's rd., Pancras rd.
January 4th, 1872.

COOKESTOWN HOUSE, INSTITUTED FOR THE MEDICAL TREATMENT OF THE INSANE OF BOTH SEXES.

This highly respectable Mansion in no respect resembles, either internally or externally, what is usually known as an Asylum.

The Demesne, Conservatories, Graperies, and Grounds are unusually extensive, and in good condition.

There are Billiard Tables for both sexes, with indoor and outdoor amusements, including Vehicles.

Cookestown House is within three miles of Carrick-on-Suir Station, with a like distance from Fiddown, both on the Waterford and Limerick Lines, and in connection with the G. S. & W. and Kilkenny Lines.

For terms, and Form of Admission, apply to the Resident Physician.

JOHN PEPPARD, M.D., &c.
Cokestown House, Piltown, co. Kilkenny.

CANCER HOSPITAL, LONDON AND BROMPTON.—There is a vacancy at this Hospital for a RESIDENT HOUSE-SURGEON. Candidates must be registered Members of the Royal College of Surgeons of England, and thoroughly conversant with the use of the microscope. Honorarium at the rate of Fifty Guineas per annum, with board and residence. Applications with testimonials addressed to the chairman of the Weekly Board, 167 Piccadilly, to be sent in on or before the 22nd inst.

By order, H. J. JUPP, Secretary.
2nd January, 1872.

MEDICAL DEBT RECOVERY OFFICES,

13A, Great George street, Westminster, S.W.

MR. W. T. PEACOCK, DEBT COLLECTOR and ACCOUNTANT, begs to intimate that he continues to devote his personal and careful attention to the RECOVERY of DEBTS.

MEDICAL PRACTITIONERS, in TOWN or COUNTRY, by availing themselves of Mr. PEACOCK'S services, will ensure an economical prompt, and efficient mode of recovering their outstanding accounts.

Terms and references on application, or sent post free.

The Medical Press and Circular

OFFERS UNUSUAL ADVANTAGES

FOR the Insertion of announcements, from its extensive and largely increasing circulation in each of the three divisions of the United Kingdom and the Colonies. Being also supplied to the Hospital Libraries, &c., it will be found a most valuable medium for Advertisements of Books, Vacancies and Appointments, Sales and Transfers of Practices, Surgical Instruments, Chemicals, and Trades generally.

The scale of charges is as follows:—

Seven lines and under	£0	4	0
Per line afterwards	0	0	6
One quarter page	1	5	0
Half-page	2	10	0
One do.	5	0	0

When advertisements are given for a series of insertions, a very considerable reduction from the above scale is made.

☞ Advertisements for Insertion in this Journal must be at the OFFICE, on SATURDAY, by Two o'Clock.

ON THE OCCURRENCE OF SYPHILITIC GONORRHŒA; OR URETHRITIS, FOLLOWED BY CONSTITUTIONAL SIGNS, WITHOUT THE FORMATION OF A URETHRAL SORE?

By J. Morgan, M.D., F.R.C.S.I.,

Surgeon to Mercer's and to the Westmoreland Lock Hospitals, Professor of Surgical and Descriptive Anatomy, R.C.S.I.

While indurated chancre apparently occurs in the urethra itself, yet it must be admitted that we want more direct proof (by absolute examination and inspection of the opened canal) of the formation of this sore. The induration, and the history, with the sequence of constitutional signs, leads to the conclusion that such an accident actually happens, where a "knob" in the urethra may be so distinct, that it can be projected by the patient, between his finger and thumb; though from the depth at which the sore may form, it may be difficult or impossible to inspect it, even with artificial aid. There are also other lesions with which this may be confounded, such as with a soft or chancroid sore, or with an inflamed follicle of the urethra, or with the induration sometimes excited by the frequent use of strong astringent injections.

The occurrence of a chancre in the urethra may be at all events suspected, when symptoms of gonorrhœa, of unusual mildness, occur in a patient who is affected for the first time; and if, instead of the pain being that of the urine passing over an inflamed region known as the "specific distance" confined to the last two inches of the urethra; the patient describes one fixed region or point which he can usually indicate with tolerable exactitude.

With this form of chancre or initial lesion, there is usually a more defined circumscribed hardness, the tumour is capable of being made prominent and pea-like along the urethral wall; the glands of the groin may indicate the constitutional advent of the poison by their enlargement and hardness, and a dense lymphatic may be found along the penis. The diagnosis of such concealed sores is by no means easy, for, though an indurated spot can be ascertained; in many cases no constitutional signs appear; while, on the other hand, from gonorrhœa, without any such palpable indication; constitutional signs beyond doubt occasionally do follow, as I can testify from my own experience. We have been too ready, it appears to me, to assume the existence of larval or urethral chancre as proved, and to lay aside the idea of a syphilitic or infecting gonorrhœa. As I have pointed out (*a*) that a purulent discharge in an infected female can produce, when inoculated, undoubted soft or chancroid sores, capable of auto-inoculation and *re*-auto-inoculation in syphilised subjects, and that this discharge conducts itself as other secondary products are known to do—it is not unreasonable to conclude that did such a secretion communicate a gonorrhœa, it might, as derived from a syphilitic source, be capable of conveying constitutional infection, or, it may be, of producing but the local effects of the chancroid or soft sore. How far, in fact, an indurated or tender spot within the urethral canal indicates the absolute occurrence of a concealed sore, is still (notwithstanding the power of such an authority as Ricord) dubious; any impartial observer who examines the drawings illustrating internal ulceration of the genito-urinary tract (*b*) will hesitate, I think, as to the nature of the ulceration being of a primary form, and as a gonorrhœa in a syphilitic female is undoubtedly fully capable of auto-inoculation, there is not much difficulty in supposing that should a male receive a gonorrhœa from such a source it could in its turn be capable of producing an auto-inoculation, a power which is now proved not *necessarily* to be confined to the chancroid sore; and if the not unusual occurrence of a tender and swollen spot, or lacuna in the urethra, be superadded, we have all the known phenomena of a larval or urethral sore. While it must be admitted that the exciting cause of gonorrhœa seems to depend not only on a specific inflammation, but on various leucorrhœal and acrid discharges; the question arises—is there a syphilitic gonorrhœa, without the ascertainable

---

(*b*) *Iconographic Record*, plate 8.

existence of a chancre inside the urethral canal? or does the occurrence of a gonorrhœa followed by constitutional signs, entail the necessary occurrence of a urethral sore, the essential existence of which is so often fallen back on in dubious cases, as explanatory of the infection of the system.

It is remarkable that females who are admitted to hospital for primary syphilis, will have no discharge, yet after a few weeks, while *still* in hospital, when marked constitutional signs evolve themselves, a vaginal discharge is frequently complained of, and is copiously evidenced on speculum examination—synchronous with the formation of rashes, patches, and other constitutional evidences.

The question of specific gonorrhœa in the male has received lately much interest from certain experiments that have been performed by Mr. Hammond in America; and as they are confirmed by others performed by Wallace many years ago in this city, the chain of evidence connecting the formation of gonorrhœa in certain cases, with syphilis proper, or with chancroid (as, I believe, a derivative from syphilis modified by descent), becomes tolerably complete: and in the formation of gonorrhœa from the threefold sources of syphilitic, specific, and accidental female discharges, we have some explanation of the unaccountable difficulties that are experienced in the cure of some cases, in comparison with others, how it is that constitutional signs will *occasionally* follow a gonorrhœal discharge, and how it is that mercurials given at hap-hazard, have succeeded in curing what has defied other remedies. Hammond's (*a*) statements go to prove some very important facts.

1. That the virus of an infecting chancre deposited in the urethra, will originate inflammation and discharge, without the necessary formation of a sore, unless there be an accidental abrasion.
2. That this is a syphilitic gonorrhœa, capable of evolving constitutional signs.
3. That the virus of soft chancre when deposited in like manner, gives rise to an inflammation and discharge, without the necessary formation of a local sore; that this is capable of giving a similar discharge to another person, but is not followed by specific signs.
4. That discharges may originate from stimulating food, venery, acrid applications, injuries, ascarides, instruments, without specific character; (to this I may add what seems to me a cause; ulcerations of the uterus when irritated and secreting acrid discharges).

Hammond relates examples of syphilitic gonorrhœa, illustrated by observation and direct experiment, from the indurated sore, as in the following series:—

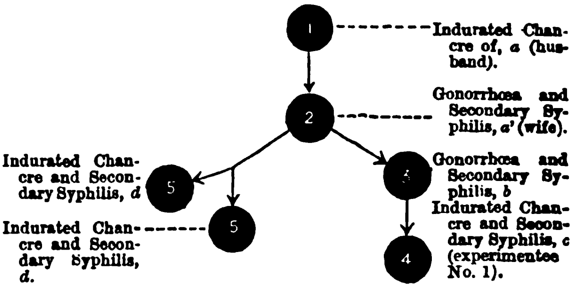
a.—A husband with indurated chancre of nearly four week's date communicates gonorrhœa to his wife, without indurated inguinal glands; she however became syphilitic.

b.—She has connection with another man, and gives him a gonorrhœa only, followed by constitutional signs, without indurated inguinal glands.

c.—A portion of this man's urethral discharge inoculated on a perfectly healthy person, who voluntarily submitted himself, causes an indurated sore, and constitutional signs.

d.—Two other healthy men inoculated with the vaginal discharge of this woman have indurated sores and constitutional signs.

As by the observations I have carried out, I show that the vaginal discharge of syphilitics can produce on syphilitics, a sore, which comports itself, as does also the indurated chancre, when inoculated on syphilitics, I see no difficulty in understanding that the discharge as transplanted from the female to the urethra of the male *b*, was capable of producing infecting sores in the admittedly virgin soils of cases *c* and *d*, the woman *b* being herself the syphilitic source. The subjoined scheme after Hammond well illustrates the chain of evidence:—



1
Indurated Chancre of, *a* (husband).
2
Gonorrhœa and Secondary Syphilis, *a'* (wife).
Indurated Chancre and Secondary Syphilis, *d*
5
3
Gonorrhœa and Secondary Syphilis, *b*
Indurated Chancre and Secondary Syphilis, *d.*
5
Indurated Chancre and Secondary Syphilis, *c* (experimentee No. 1).
4

The following direct proofs of soft chancre producing gonorrhœal discharge are also produced by Hammond:—

August 20, 1859.—J. H., suffering from soft chancre, and with suppurated bubo. With his own consent a catheter was introduced, into the *cul de sac* of which Dr. Hammond had put a quantity of pus from his chancre; an inch into the urethra, keeping it there some minutes, and allowing the matter to escape.

August 22.—Had pain in urinating and tenderness at a point one inch and-a-half down. Later in the day some drops of muco pus escaped.

August 24.—A discharge was well established, the urethra was then speculised, but no sore was detected. He was inoculated on each thigh, in one place from the sore, and in another from the urethral discharge. That from the sore produced a sore; the discharge was abortive.

August 30.—The bubo was opened, and produced a sore by inoculation.

August 31.—The urethral discharge had become profuse, inoculation again tried was negative.

September 4.—Inoculation repeated was also negative.

Another case, tested in like manner from a soft chancre of the prepuce, and another from the one on the dorsum of the penis, produced similar phenomena. The converse of this experiment he also performed, and from a gonorrhœa, produced by careful inoculation, a soft chancre.

Mr. Wallace, in 1835, also performed some very remarkable experiments on this subject, as in the following examples:—

Artificial Production of Gonorrhœa from Chancroid Sore.

M. Connor, Feb. 21, suffering from a primary sore on the prepuce and an ulcerated bubo. Passed lint dipped in the matter of J. Gavan's sore (phagedænic) and in his own matter (chancroid) into his urethra, followed by urethral discharge.

Feb. 24.—Much more urethral discharge.

Artificial Production of Gonorrhœa from a Secondary Ulceration.

R. Durham (a thoroughly syphilitic patient).—"All his symptoms well, except an ulcer on his leg, with white surface, edge nibbed and sharp, and its margins perpendicular."

Matter from this was introduced into the urethras of both

Feb. 18.—P. Fennell, æt. 16, with primary ulcer and large bubo.	Feb. 18.—P. Phillips, æt. 60. Not having had a gonorrhœa for years.
Feb. 21.—Does not complain of his urethra more than he did.	Feb. 21.—No effect. Repeated the matter.
Feb. 25.—Says there is no more running from the urethra.	Feb. 25.—Discharge from the urethra.
	April 15.—Discharge still continuing from the urethra.

The following case shows, on the other hand, that the result from secondary ulcerations was not invariable:—

Jan. 19th, 1835.—Joe Preston, æt. 14 (brother of James Preston, under treatment for rash and secondary ulcers)

(*a*) Page 296.

applied with a sore on left side of his scrotum, the size of a shilling, scarcely deeper than the skin—more pulpy in the centre—it commenced like a little blister, or as if the skin had come off it, the sore is granulating at the circumference so abundantly that it has a rim round, and a hollow in the centre. There is a tumour in the left groin, the cellular around it is engaged. The shape of the sore is oval, 1½ inch long, and ¾ inch broad, he has a rash, and there is beside on his head and lower back, several spots or scabs of a flat appearance (calls them superficial ulcerations). He has the sore and the spots about two months; he has not pains, or sore throat; he is of opinion he got the disease by sleeping with his brother.

Jan. 15th.—Primary and secondary matter together was passed into his urethra.

Jan. 23rd.—His urethra has not inflamed.

On Jan. 20th, the matter of his ulcer was passed into the urethras of four other patients. In two there is no further report, and in one it is stated, no effect was produced, and in another on Feb. 21st, the pipe of urethra felt hard, and there seemed to be an oozing. Feb. 24th.—His urine had some difficulty in getting out of the passage. (No further account.)

Jan. 25th.—Surface of the ulcer is above the surrounding level, says he has headache, on the surface of the body several scabs, which cause superficial ulcers, which resemble those of his brother.

Feb. 5th.—The sore may be said to be healed, mouth not sore.

Feb. 25th.—This boy now applies, with phymosis, pain in urinating, discharge; says these symptoms began about three weeks ago, being twenty days from the introduction of the matter. Scrotum is well, with exception of a little hardness; all the spots on his back and body are well, but one on his right hip, and it has the characteristic appearance of a superficial ulcer surrounded by a purple areola.

It is thus shown by direct observations that the purulent or mico-purulent discharge in a syphilitic woman is capable of producing a sore.

That chancroid or chancrous matter, passed into the urethra will produce gonorrhœa, and be in turn capable of inoculation.

That the matter from secondary syphilitic lesions when introduced into the urethra, can produce a gonorrhœa. This last experiment bears out a point not so unusually observed in practice, that a gonorrhœa appearing late after a suspicious intercourse is usually one specially refractory to treatment.

◆

CLINICAL LECTURES ON DISEASES OF THE EYE,

DELIVERED AT THE ADELAIDE HOSPITAL.

By H. R. Swanzy, M.B., L.R.C.S.I.,

Ophthalmic Surgeon to the Hospital, and Surgeon to the National Eye and Ear Infirmary; late Assistant to the late Professor Von Graefe, Berlin.

LECTURE V.—*Cataract.*

Gentlemen,—According as cases of cataract presented themselves here, I have taken occasion to direct your attention to those points in diagnosis and prognosis which each of them seemed most suited to illustrate. To-day we have before us a rather unusual case, and I wish now, in connection with it, to give you a *resumé* of what I have already said from time to time, and to add some remarks which may be of practical value to you.

The cataract of old age or senile cataract, is the most common form of this disease. It usually attacks persons over fifty years of age. In it the central portion, or nucleus of the crystalline lens is the most opaque and hardest part, while the cortical substance is much more translucent, even when the cataract has become quite ripe. This depends upon the physiological changes which take place in every crystalline lens with advancing years. In the youthful crystalline the central part is not more consistent than the cortical layers; but, before middle life is attained, a distinct nucleus of a firmer texture is found, which becomes more marked at later periods. In old age, too, the lens, and especially its nucleus, obtains an amber tint, which is sometimes of so deep a shade that you must be careful not to mistake it for a cataract. Senile cataract, indeed, appears to be one of those conditions which stand on the foundary of what is pathological and what is physiological. We may yet, no doubt, have much to learn as to the cause of the affection, but, so far, we know that cataract frequently makes its appearance in persons otherwise perfectly hale, and, therefore, when you find it in some who have suffered much from gout or rheumatism, it would be irrational to seek its cause in the latter or any other concomitant constitutional disease. Nor has the microscope been as yet successful in demonstrating changes in the choroid or vitreous humour, which would account for the alterations in the lens on the supposition of a locally impaired nutrition. We may, therefore, be not far astray in regarding senile cataract as an exaggerated physiological condition, a consideration which does not take it out of the category of diseases, interfering as it does with the functions of the organ. Similarly, a certain amount of chronic enlargement of the prostate gland is extremely common in old age, but is not regarded by surgeons as a disease until it attains such a degree as to impede the functions of neighbouring parts.

Senile cataract may commence in the nucleus, or in the cortical portion of the lens, or simultaneously in both. These forms, however, which commence with fine stripes in the edge of the lens, while the nucleus remains clear, are usually very slow in their progress, so much so, indeed, that if your patient be of an advanced age, it may be more judicious to refrain from mention of this condition of the eye, for he will be very apt to outlive this cataract. Broad stripes in the corticalis with accompanying opacities of the nucleus indicate a rapidly advancing cataract. In every elderly person who comes to you complaining of his vision, you must carefully examine the crystalline lens. You must do so by daylight, by the reflected light of a lamp with the mirror of your ophthalmoscope, and by means of the oblique illumination. According as the opacities in question, if they be present, are more or less intense, you will discover them best by one or other method. In using the reflected light to discover incipient cataract, it is a mistake to have it too brilliant, for then the more translucent opacities may escape detection. To examine the periphery of the lens which is concealed by the iris, you must direct the patient to look strongly to one side, or upwards or downwards, while you look into the eye from the opposite direction. When a senile cataract is quite ripe, the entire of the cortical portion has become opaque, and with the oblique light a yellow reflexion is obtained out of the centre of the lens from the hard nucleus.

This is the most favourable form of cataract for operation, fully ninety-five per cent. of such eyes being restored to vision by means of Graefe's peripheral linear extraction. By means of this method, which is you see practised here, the most infirm person may be operated on. In the days of the flap extraction many bodily infirmities afforded contra-indications to its performance, as it entailed confinement to bed in a horizontal position for a lengthened period. If the condition of the patient renders it impossible or undesirable that he should be confined to bed, he need barely lie down for more than a few hours after the extraction by Graefe's method; and in no case which runs a favourable course, need the patient remain in bed for more than three or four days. I do not now intend to take up time by a description of the various steps of the operation which you have seen performed, and which you will have another opportunity of witnessing in this case. To have a successful result, it is quite as necessary, in my mind, that the after treatment of the case be properly conducted, as that the operation itself be correctly performed. Graefe not only developed this method of extraction, but also the treatment best adapted to it; a circumstance which is very generally ignored.

Immediately after the operation the eye is carefully padded with fine charpie or French wadding, in such a way that no part of the globe is pressed on more than another; then, three turns of a narrow flannel roller are made with a gentle, but firm and equal pressure over the eye and round the head, in the manner with which you are acquainted. The patient is then comfortably settled in bed, and the room darkened. The pain of the wound should not be very severe, and should not continue longer than four or five hours; in either event you should administer about the eighth of a grain of morphine hypodermically in the corresponding temple. Pain, in all affections of the eye, is a symptom which, as a general rule, you must combat, for in itself it gives rise to irritation. In eight hours, or thereabouts, after the operation the bandage should be changed, with the object of removing the slight secretions, blood clots, &c., which are apt to collect between the edges of the lids, and which, if left there might, by their decomposition, afford the starting point for suppuration of the wound. It is not advisable, however, to open the eye or expose the wound at this early period. Between the twelfth and twenty-fourth hours is the period when you must be on the look out for anomalies in the process of healing. During this period when the course is normal, no pain or disagreeable sensation should be experienced by the patient, or at most, only an occasional and momentary "pricking." Any continued pain at this time, no matter how slight, must be regarded as a bad symptom, and be at once attended to. The bandage must be removed, any collection of tears under the lids given egress to, and if there be any swelling of the lids as counter-irritation, they should be lightly touched externally with mitigated lapis which is then immediately neutralised with a solution of salt. If the pain still continue, a hypodermic injection of morphine should be given, and if this does not attain the desired end, then in case your patient's strength admit of it, you should employ a venesection from the arm to the amount of four or five ounces, this should be followed by a calomel purge, and—if the interval since the previous one is long enough—another morphine injection, a very firm and exact bandage being applied. When the patient is not healthy enough to admit of a venesection, you must confine yourselves to the other means I have mentioned. With this aid you will, in a vast majority of cases, succeed in cutting short the suppurative process, which is just about being set up in the wound. But I must guard you against the fallacy of supposing that some delay in their employment is of no consequence. If you are to effect anything you must resort to them early, before suppuration has set in, for once it has done so your skill will be of little avail. You will not find that this treatment is one much adopted by ophthalmic surgeons; but, it was laid down upon the basis of a most extensive field of practice by Graefe, who was endowed with remarkable powers of clinical observation, and I can testify to its value myself. That which most surgeons would be likely to take exception at, is the changing of the bandage so soon after the operation, and yet Graefe considered this one of the most important points. After the flap operation the bandage used not to be altered for some days. The venesection, too, is likely to be regarded with disfavour by many, in consequence of its being now so out of fashion. In this particular instance, I have no doubt of its frequent efficacy; and further, I believe you will see a reaction in favour of venesection in general medicine and surgery before many years, but with more restricted and precise indications than formerly. Among the many advantages afforded by the peripheral linear extraction, is the short period during which the surgeon has to be on his guard against suppuration of the wound; from the twelfth to the twenty-fourth or thirtieth hour being the time when it occurs, and never any later. With the flap operation, the eye could not be pronounced safe from suppurative reaction for several days.

Previous to extracting a cataract, you should endeavour to ascertain whether the condition of the retina, &c., is normal; in senile cataract it will generally be found so. Complications, however, which are more common in these cases are conjunctivitis, and obstructions in the lachrymal canals and nasal ducts. These you should in every case look for, and, if present, you must endeavour to restore the normal condition, or something approaching it, before extracting the cataract; otherwise, the muco-purulent secretion collecting under the bandage is very apt to produce serious anomalies in the healing process.

I have told you that old age is the most frequent cause of cataract. The disease, however, is by no means rare at other periods of life. You will often find persons of thirty-five and forty afflicted with it, and you will not seldom observe that its occurrence at this age depends upon an hereditary tendency, some of the patients' forefathers having some fluid from the same cause, although perhaps later in life. The cataract then is generally of a softer consistence, with a small nucleus. Its removal cannot be effected with as good a prognosis as the true senile cataract.

In diabetes, as I suppose most of you know, the lens often becomes cataractous. There is nothing in the appearance of a cataract dependent upon diabetes to distinguish it from any other, and it is consequently a good general rule to examine the urine of every cataract patient for sugar. Diabetes cataract may be removed with success, and it will always be your duty to remove it unless a fatal termination to the general disease appear imminent. We know how long patients sometimes linger under this disease, and it surely would be inhuman not to afford them the boon of vision for the last few months of their existence, when it may be given them with so little pain. My own experience of extraction in diabetes cataract is not sufficient to form from it an estimate as to the percentage of successful cases. It happens that I have not yet seen an unsuccessful one. Graefe found that in twenty cases of cataracta diabetica, sixteen recovered their vision by extraction.

Cataract may be produced traumatically; the most common injury being that caused by the entry of a foreign body into the eye through the cornea, and then into the lens itself. When the capsule of the lens is opened, the action of the aqueous humour on the fibres of the lens is sufficient to make them swell and become opaque. The foreign body may have been a large one, which was again withdrawn from the eye, or it may have been a small atom of metal which continues in the eye. These are often most delicate points to decide, and they are of the utmost importance, as, in case of a foreign body lodging in the eye, the ultimate prognosis for the organ is very serious indeed. You will arrive at a conclusion by the history of the case and by an examination of the eye itself. Besides penetrating wounds, blows on the eye are sufficient to cause cataract, whether given by the fist or by the cork of a soda water or champagne bottle, or by the end of a billiard cue, the patient standing behind the player while he is making his stroke. It is probable that in these cases the capsule of the lens is ruptured in some place by the concussion, as otherwise it would be difficult to understand how such injuries could cause opacities of the lens.

Cataract may depend upon deep-seated disease in the eye, *e. g.*, detachment of the retina, certain forms of choroiditis, retinitis, and irido-choroiditis. In most of these cases the external appearance of the eye gives no clue to the condition of things lying behind the cataract. The ophthalmoscope of course is of no use, in consequence of the opacity of the lens; and it is by the state of the functions alone that we can determine whether the cataract be complicated or not. If you hold a muffed milk glass close before your eye you will be able to realise the disturbance to vision caused by a fine uncomplicated cataract, and at from one to two feet you will be able to distinguish the light of a gas flame turned down to the lowest, and to see the motion of the hand in a favourable light at a foot or so from the eye ; in a dark room you will also be able to tell from what direction the light from the lamp comes ; this latter we term the "power of projection." If in any of these particulars a cataractous eye be not up to the mark, you must be very suspicious of the presence of complications, especially so if the projection be incorrect or defective, for this shows that that part of the retina upon which the light falls is probably diseased. Under such circumstances you would either not extract the cataract at all, or, if you thought the disease in the fundus oculi to be of limited extent, you might do it, having prepared your patient for an imperfect result.

The patient before you is aged eight-and-twenty. In the right eye there is a cataract which is shrivelled with a thickened anterior capsule. The power of perception of light in this eye is very insufficient, and the power of projection is wanting in every direction, there can be no doubt, therefore, that there are extensive complications in the fundus, of what nature I am not prepared to say. There is the history of an injury to the eye some years ago, and, very possibly, both the cataract and the deeper complications depend upon it ; indeed, if it were not for the condition of the other eye, I should almost certainly be of that opinion. In the left eye she has a mature soft cataract of some months' standing, and, as well as we can make out by a functional examination, the fundus is normal. This is very remarkable in so young a subject, and is rendered still more so if the other eye be taken into consideration. The urine is normal, and there is no hereditary tendency. It is therefore indicated to operate upon the left eye, but not on the right.

Before I conclude I may mention two other forms of cataract which you will meet with—namely, lamellar or zonular, and congenital. The first affects only certain layers of the lens, the others being left quite intact. The layers affected are generally those around the nucleus, so that the latter and the cortical substance remain clear. If the opacity be not very extensive the patient may have very fair vision still, particularly with his back to the window, or when he shades his eyes with his hand, so that, the pupil dilating, he sees through the clear edge of the lens. This too suggests one mode of improving the vision of these persons, namely, by forming an artificial pupil in the nasal portion of the iris, through which the patient may now see in any light. But when the opacity is extensive an artificial pupil would do no good, and then you will generally find the best proceeding to be that called division or breaking up of the cataract. A fine needle is pressed through the cornea into the capsule, and the latter torn to a slight extent ; the anterior layer of the lens is broken up a little with the needle. In this way the aqueous humour is admitted to the substance of the lens, which gradually softens and becomes absorbed. This operation requires to be repeated frequently before the entire lens disappears, and the entire process, which occupied several months, is sometimes attended with dangers of which I shall speak to you when next I have a case of the kind under treatment. Zonular cataract most commonly appears after the first dentition, and it is a curious fact that the subjects of it have usually suffered from convulsions during teething. The affection may also be congenital.

Congenital cataract is not uncommon. It is a soft cortical cataract, and it is doubtful to what circumstances it owes its formation. Generally speaking these are favourable cases for operation by division, provided the patient be not too old, but by the sixth or seventh year the retina, from never having been used, becomes rather inert. It is advisable therefore to operate early, if possible before the first dentition. Much mischief is done by postponing the operation until the tenth or even fifth year. It is a remarkable fact, showing how necessary practice is for the development of the functions of a part, that if at ten years of age a cataract is produced by trauma, you may obtain very good vision for the patient if you operate even forty years afterwards, but in congenital cataract the result will be but very wretched in the fifth year after birth.

This, gentlemen, is a short sketch of some of the principal points in connection with the subject of cataract, which I shall endeavour to develop more minutely as circumstances permit.

◆

UTERINE NEURALGIA AND ITS CHIEF COMPLICATIONS:

THEIR PATHOLOGY AND TREATMENT.

By John Chapman, M.D., M.R.C.P., M.R.C.S.,
Physician to the Farringdon Dispensary.

(*Continued from Page* 8.)

An instructive case of this kind is reported by Professor Bedford, of New York (a):—Mrs. H., æt. 23, the mother of one child, three weeks' old, complained of great distress in her womb whenever she allowed her infant to suck. She had been married about eighteen months; had always been a healthy woman, and never suffered from pain in her womb before the birth of her child. The pain left her on each occasion when the child finished sucking, and, as time advanced, it became less severe. It is probable that in this case the slight reflex cause of the neuralgia—viz, the child's irritation of the nipple—would not have sufficed to produce the pain had not the womb been in that state of excessive sensibility, consequent on parturition, only a short time before the pain was induced. We know that, as a general rule, suckling speedily after the birth of the child causes a perceptible reflex influence on the womb, and promotes or completes its contraction—pain, more or less severe, being in many cases associated with the process.

The pathology of irritable uterus or uterine neuralgia has engaged a large share of professional attention, but has received, as it seems to me, no corresponding amount of elucidation. "What is the nature of the irritable uterus ?" inquires Dr. Gooch. "It is not acute inflammation ; for that would run a far shorter course, and end in certain known consequences. It is not chronic inflammation ; for that is a disorganising process, and slowly but surely alters the structure of the organ in which it goes on. Both in chronic inflammation and in the disease which I am describing, there is a morbid state of the nerves, indicated by pain, and, sometimes, at least, a morbid state of the blood-vessels, indicated by their fulness ; but the substances effused by chronic inflammation show that in this there is something additional in their actions, and, consequently, in the state of the vessels. The disease which I am describing resembles a state which other organs are subject to, and which in them is denominated irritation. Thus, surgeons describe what they call an irritable tumour of the breast. It is exquisitely painful ; an ungentle examination of the part leaves pain for hours ; it is always in pain, but this is greatly increased every month, immediately before the menstrual period. Although apprehensions are entertained of cancer, it never terminates in disease of structure. It is represented as a very common disease. Mr. Brodie describes a similar case in the joints. It occurs chiefly among hysterical females : it is attended by pain, at first without any tumefaction, but the pain increases, and is attended with a puffy, diffused, and trifling swelling ; the part is exceedingly tender. This assemblage of symptoms, lasting a long time, and being often a little relieved by remedies, occasions great anxiety, but there never arise any ultimate bad consequences. 'The disease,' says Mr. Brodie, 'appears to depend on a morbid condition of the nerves, and may be regarded as a local hysterical affection.' These painful states of the breast and of the joints appear to be similar to that which I have been describing in the uterus; similar kinds of constitutions which they attack; similar in pain, in exquisite tenderness, in resemblance to the commencement of organic disease, and in proving ultimately to be only diseases of function."

(a) "Clinical Lectures on the Diseases of Women and Children." New York. 1856. P. 316.

Dr. Robert Lee, who quotes the above passage, says,—"Dr. Dewees, whose attention has been particularly directed to the pathology of this affection, does not consider this view of the subject correct, and it is certainly very difficult to discover any analogy between a tumour of the female breast, or joints, and an affection of the uterus, depending solely upon a morbid state of its nerves." (*a*) Dr. Lee regards the disease in question as "chronic congestion and inflammation of the uterus." Dr. Ashwell held a like opinion. Referring to Dr. Gooch's doctrine, which, he says, requires "more proof than has hitherto been adduced," he adds—"This accurate observer founded his views on analogy, and on the lengthened period of ten years, during which, having carefully watched the progress of certain cases, he found the uterine organisation still unaltered. The analogical part of the opinion is unsatisfactory, and must remain so till the nature of hysteria is developed, and till the affections from which this pathology is deduced are more clearly proved to be not at all dependent on inflammation. That the disease in question should be regarded as a modified inflammation of the cervix uteri, is a view, not only in accordance with symptoms, but with the results of the most successful treatment. It is difficult to understand that there shall be redness, which I have several times seen by the speculum, heat, permanent pain, and tenderness of the neck of the uterus, a glandular part, without believing that its vascular and nervous structures shall have undergone some changes." (*b*) The question at issue is, after all, simply a question of fact: Dr. Gooch, while freely admitting that, in one class of cases of irritable uterus, "congestion is an essential part," also maintains the existence of another class of cases in which no sign of congestion or inflammation is discoverable. We know quite well that pain of the most agonizing kind, persisting, with but slight intervals of relief, for years, and associated with extreme sensitiveness and tenderness—evinced by pressure on the affected part, may manifest itself in various parts of the body without any congestion or sign of inflammation; now, the recognition of this fact should, I think, not only remove any *primâ facie* difficulty in admitting the possibility of protracted uterine pain unassociated with inflammation, but should, in fact, lead us to surmise the existence of such pain; and, indeed, its existence is affirmed by several competent observers. Professor Bedford, commenting on a case of what he calls "neuralgia of the cervix uteri," makes use of these words:—"On an examination, *per vaginam*, I have recognised no change whatever in the position or structure of the uterus; the organ is in all respects natural, except in one particular—in pressing with my finger on the os uteri the patient complains of suffering." He adds,—"I have satisfied myself, by this mode of exploration, that the case before us is what is termed neuralgia of the neck of the womb, an affection oftentimes mistaken for some other disorder; *and there is no disease with which it is more likely to be confounded than chronic congestion of the uterus.* Uterine neuralgia is sometimes symptomatic of disease of the uterus, such as enlargement, ulceration, &c.; sometimes, also, of displacement. Again, it will occasionally present itself as a primary affection *entirely unconnected with any lesion of structure.*" (*c*) This statement I believe to be true, and I am confident that the views of the subject first formally propounded by Dr. Gooch are essentially correct. Moreover, a due consideration of the pathology of neuralgia which I hold to be alone consistent with all the facts of the disease, and which I have fully explained elsewhere (*a*) will, I believe, afford a ground of conciliation of his views with those of the eminent physicians to whose criticisms I have just adverted. For, by the light of that pathology, we see that in cases of neuralgia the symptoms of inflammation may be present as collateral or secondary phenomena, that they may appear in any case, that they ought to be carefully looked for in every case, and that in a large proportion of cases they are more or less decisively perceptible. Dr. Gooch needlessly weakened his own argument, and strengthened that of his adversaries, when he maintained that all the symptoms of inflammation of the uterus may be present without the existence of inflammation. He assumed this position because, while holding with other pathologists of his time that acute inflammation runs a short course, and that chronic inflammation is a disorganising process, he found that, as a matter of fact, neither of these conditions is represented by the disease he called "irritable uterus," which, as a rule, neither runs a short course nor "is a disorganising process," but which, nevertheless, is often associated with symptoms of inflammation. Had he understood what is the *rôle* of the nervous system in the production of all forms—and, what he deemed, semblances—of inflammation, he would have dismissed the idea that chronic inflammation is, *necessarily*, "a disorganising process;" and, so far as the question of inflammation is concerned, would simply have divided cases of "irritable uterus" into two classes—those presenting symptoms of inflammation, and those not presenting them.

The existence of uterine nerves was first demonstrated by Tiedemann, who published figures of them as he saw them in the case of a woman who died six days after delivery; but his description gives no adequate idea of the large extent to which the womb is actually innervated. Our present knowledge of the neural anatomy of that organ is mainly due to the elaborate researches of Dr. Robert Lee, and knowing as we now do, by his aid, not only that it is abundantly innervated, but also the mode of its innervation, we understand its physiology far more completely than before, while the flood of light cast on its morbid processes by what has been ascertained of its neural anatomy and physioloy has inaugurated a new era in the history of uterine pathology. The amount of Dr. Lee's contribution to it may be most fitly stated in his own words. "I have demonstrated," he says, "that the human uterus possesses a great system of ganglia and nerves, connected with the sympathetic and spinal cord, which enlarges with the coats, blood-vessels, and absorbents during pregnancy, and which returns, after parturition, to its original condition before conception takes place. It is chiefly by the influence of these ganglia and nerves that the uterus performs the varied functions of menstruation, conception and parturition, and it is solely by their means that the whole fabric of the nervous system sympathises with the different morbid affections of the uterus. If these ganglia could not be demonstrated, its physiology and pathology would be completely inexplicable. . . . I have demonstrated that every artery distributed throughout the walls of the uterus and heart, and every muscular fasciculus of these organs, is supplied with nerves upon which ganglia are formed.

"In amenorrhœa, chlorosis, dysmenorrhœa, menorrhagia, hysteria, hysteralgia, sterility, all the functional disorders of the unimpregnated uterus, and, in many of the diseases of the gravid uterus, the slightest reflection on the symptoms would lead us to conclude that these are nervous diseases. The local and constitutional phenomena of these diseases would be inexplicable, if we did not know that the uterus has an extensive system of ganglia and nerves, great nervous centres, connected with the spinal cord. The treatment of these diseases cannot, without this knowledge, be conducted upon sound physiological and pathological principles." (*b*) The existence of the uterine system

of nerves is now becoming generally recognised, and the reality of Dr. Lee's discoveries, as described by himself, has been, more or less completely confirmed by the results of the independent researches of Tiedemann, Müller, Herschfeld, Boulan, and other inquirers in this important field.

But though, as Dr. Lee rightly observes, without a knowledge of the extensive system of ganglia and nerves of the uterus, "its physiology and pathology would be completely inexplicable," I am not aware that either he or any other physician has explained the precise *modus operandi* of those ganglia and nerves in effecting those numerous processes of the uterus comprised within the wide range of both its physiological and pathological functions. In so far as the pathology of irritable uterus, and of its associated disorders, is concerned, I shall therefore, attempt to explain in detail here what the *rôle* of the nervous system is, and will, in the first place, recur to the discussion of the question of the nature and significance of the symptoms of inflammation often present in cases of "irritable uterus."

The presence or absence of these symptoms in any given case of uterine neuralgia is determined by the conditions of those nervous centres immediately presiding over the textural nutrition, as well as over the blood-supply, of the womb: if the energy and excitement of the nutritive (positive-motor) nerve cells be predominant, the nutritive processes will be so intensified and augmented as to constitute uterine inflammation of some grade.(*a*) If, on the contrary, the energy of the vaso-motor (negative-motor) nerves be predominant, those processes will be relatively in abeyance, and the uterine arteries will be so contracted as, in fact, to produce uterine anæmia of some grade as a concomitant of the neuralgia; and, in either case, the condition mentioned being once established in the nervous centres in question, may, with slight fluctuations, persist for years; and hence, if the force of the positive-motor nerves be relatively the greatest, the phenomena of inflammation may, and indeed will, be equally persistent, and yet the intensity of the process may be so subdued as to continue for years without effecting any disorganisation. If these two forces are fairly balanced they may, I apprehend, be morbidly intense without producing in the womb perceptible organic change of any kind.

Having shown that the presence of congestion or inflammation in cases of irritable uterus is no bar to the consideration of such cases as are essentially neuralgic, and that, on the contrary, congestion or inflammation is likely to occur as a concomitant or secondary affection in a certain proportion of cases of uterine neuralgia, I now proceed to explain the symptoms of the malady *seriatim*.

Pain is, of course, as the name—neuralgia—implies, the chief feature of the disease. That the sensory nerve-cells related to the womb, and affected in these cases are cerebro-spinal is a proposition which may be admitted for the three following reasons:—(1.) It has been ascertained, anatomically, that cerebro-spinal nerve fibres are distributed to the womb; (2) prolonged uterine pain is generally accompanied not only by backache, but also by tenderness (made manifest by pressure) along the lower part of the spine]; (3.) consciousness of pain in the womb is impossible without the intervention of cerebro-spinal nerve fibres. Admitting this proposition, we are led at once to the conclusion that the chief seat of the uterine sensory nerve-cells is in the lower segments of the spinal cord. The chief point of morbid sensibility in the spinal cord in cases of uterine diseases, as well as in cases of disease of the male genital organs, I find to be about the juncture of the dorsal with the lumbar vertebræ. Now, if these statements be correct, it is evident that uterine pain may be induced by any agency capable of causing irritation, and consequent hyperæmia of that segment, or those segments, of the spinal cord containing the uterine sensory nerve-cells; and if so, the conclusion is legitimate that pain referred to, or localised by consciousness in, the womb may originate quite independently of any perceptible change in that viscus, and indeed in cases in which it is structurally and, but for the pain, functionally healthy. In short, the *proximate* cause of uterine neuralgia as, in fact, of all uterine pain, is hyperæmia of those segments of the spinal cord just indicated.

Dysmenorrhœa is the symptom next in importance to that of pain—in fact, pain is generally considered as being one of the elements of dysmenorrhœa. Certain it is that, in cases of uterine neuralgia, the pain, which during the menstrual intervals, is at all events, bearable, is so greatly increased and intensified during the menstrual process as, in many cases, to become a perfect agony. I will, therefore, premise a few words concerning this augmented pain. I incline to believe that two causes may be assigned for it—that in some cases it may be mainly due to one of those causes, in others to the other, and that in still other cases each of the two may be equally operative. (1.) During the menstrual period, which corresponds with the period of rut or heat in animals, there is a great afflux of blood, and, consequently, a tumultuous increase of nervous energy in those nerve-centres functionally related to the reproductive organs. The result is a great increase of vigour and intensity in the activity of those centres; and, of course, those of them which are sensory, feeling, as they do, with augmented acuteness, transform, in cases of dysmenorrhœa, the bearable pain, of which they were previously the factors, into the agony often associated with that malady. (2.) The second of the causes now adverted to is only a twin branch, with the one just mentioned, of a common stem: in the same way as the function of the uterine sensory nerves becomes exalted, so also does that of the uterine motor nerves, and hence the vigorous and often exceedingly painful contractions of the muscular substance of the womb. Now, these strong, slow, and involuntary contractions are of the nature of cramp, and causing pressure, as there are good reasons for believing they do, on the peripheral extremities of the uterine sensory nerves so irritate them as to cause severe pain.

But though pain is a constant element of dysmenorrhœa, and the one which commands by far the most attention, *difficulty* of menstruation is the characteristic of the malady implied by its name, and, in fact, this difficulty is two fold: there is difficulty in secreting the menstrual fluid into, and difficulty in discharging it out of, the womb. The nerves (positive motor) causing the secretory action of the uterine mucous membrane are, indeed, functioning with preternatural vigour, but they lack an adequate blood-supply from which to withdraw into the womb by the agency of that membrane, the normal menstrual fluid—normal alike in quantity and quality. That adequate blood-supply is withheld by the uterine vaso-motor (negative motor) nerves, which, also functioning with preternatural vigour, effect the more or less complete closure of the uterine arteries. Hence the difficulty in secreting the menstrual fluid, and its characteristic scantiness. The difficulty in discharging the small quantity which is secreted, and the fact that a considerable proportion of that small quantity is often discharged in successive clots, are both due to the preternatural contractile energy of the womb itself. Instead

---

(*a*) The potency of nerve-force in relation to textural nutrition is well exemplified in a case of neuralgia of the face, recorded by Dr. Handfield Jones, in which severe paroxysms of the disease "issued in actual extravasation of blood in the eye and cheek. The pain would continue very severely for forty-eight hours, then begin to remit, and, at the same time, a blush would appear in the part, which increased until there was actual effusion of blood." In connection with this interesting case, Dr. Jones mentions that "Dr. Cahen has recorded (*Arch. Géner.*, Oct., 1863) two cases showing the influence of ileo-lumbar neuralgia on the occurrence of uterine hæmorrhage." (*a*) Dr. Jones, and, if I understand him rightly, Dr. Cahen, also, regards these and like cases as evidence of enfeeblement or paresis of the vaso-motor nerves distributed to the affected parts. I am constrained, however, to dissent from this interpretation of those instructive facts. I look upon them as evidence of preternatural energy in the cerebro-spinal nerve-cells related to the affected parts—energy so potent as to cause the constituent elements of the affected tissue to attract blood faster than they could assimilate it through the peripheral arteries, notwithstanding that those arteries were more or less vigorously contracted by vaso-motor energy.

(*a*) "Clinical Observations on Functional Nervous Diseases." Pp. 4-556.

of allowing the fluid to pass quickly away as fast as it is secreted, the excited womb, violently stimulated by the nerves distributed to its muscular substance, closes its orifice with spasmodic energy, and thus shuts within itself, more or less completely, the fluid effused which, therefore, having slowly accumulated, exerts distending pressure on the uterine walls, and, at length provokes, by reflex action, such violent contractions as to effect at once the complete discharge of its contents by its expulsive efforts. If the quality of the fluid be such as to enable it to clot, or to be formed into a clot, its enforced accumulation in the womb favours and aids this process; and when it is accomplished, the expulsion of the clot involves the necessity of uterine action so vehement as to resemble very closely the throes and, indeed, in some cases, even the agonies, of labour. This remarkable phenomenon is, unhappily, a by no means uncommon characteristic of severe dysmenorrhœa.

Intimately associated, physiologically, with the symptoms just discussed is the kind of *inflammation* characteristic of uterine neuralgia: the mode of origin of this inflammation, and the determining causes of its presence or absence, have already been sufficently explained in the paragraphs criticising the divergent pathological views on the subject. I therefore pass on to the consideration of that very interesting pathological phenomenon frequently accompanying dysmenorrhœa—viz., the formation and expulsion from the uterus of what is called a "false" membrane. The immediate cause of the formation of this membrane is, I venture to assert, the intensely preternatural energy of the nerve-force distributed to the uterine mucous membrane, and presiding over its normal, as well as over its abnormal, actions. That glands and glandular surfaces (mucous membranes for example), secrete at the bidding of, and by virtue of energy derived from, the nervous system, is a proposition of the utmost possible importance by way of the elucidation of the origin of the false membrane in question, as well as of a symptom next to be discussed, and the truth of this proposition I regard as fully established. Now, I have already shown that in cases of dysmenorrhœa there is great hyperæmia of the nervous centres related to the womb—hyperæmia so great as to be morbid by virtue only of its intensity. During pregnancy there is also a like hyperæmia, but it is due to a normal cause, and results, in so far as the uterine mucous membrane is concerned, in a normal product—the decidua. In dysmenorrhœa there is a similar, but less perfectly constituted, membrane, and formed in the same way. In both cases, excessive and intense action of the nerve-force distributed to the mucous membrane supersedes its ordinary function of secreting mucus, and causes it, instead, to effuse plastic lymph: this is speedily organised, in cases of pregnancy, into the decidua; and, in cases of dysmenorrhœa, into an abortive likeness of it—the false, or dysmenorrhœal, membrane. The view here expressed concerning the nature and mode of origin of this membrane differs from that generally held by the eminent pathologists who have concerned themselves with this subject only in respect to the nature and mode of action of the force by which it is produced. Most, if not all, of them regard it as a consequence of inflammation. "We shall probably be correct," says Dr. Montgomery, "in referring such productions to any cause capable of exciting a certain degree of irritation, or perhaps of inflammation, by which a thin lamella of the lining membrane of the uterus may be cast off, or lymph poured out on its surface, which assumes a membranous texture, as we find happen in other hollow organs lined with a mucous membrane, as, for instance, in the intestines in cases of diarrhœa tubularis, and in the trachea and air-tubes; to use the words of Pouchet,—'Ce n'est q'une desquamation de sa superficie, analogue à celle qui se produit à la surface des autres muqueuses, mais pluse intense:' and hence we the more readily acquiesce in the belief that such concretions may form, quite independently of the specific stimulus of conception or of sexual intercourse, an opinion which is sanctioned by the experience of the best authorities" (*a*). In this view I entirely concur; but, while assenting to the doctrine that the dysmenorrhœal membrane is formed in the manner described in this passage, I supplement that doctrine by the important addition—viz., that the membrane is so formed solely by formative power exerted by the nervous system. It is incumbent on me to insist with especial emphasis on this supplementary doctrine because, while opening a new field of pathology, it reveals for the first time in the history of the discussion of this subject the therapeutical principle which can alone guide us to a really scientific and successful treatment of the malady in question.

Having adverted to the formation of sanguineous clots, as well as of the membrane just mentioned, I may point out that when both processes take place in the same patient, effusions of lymph and of blood may occur alternately, and that, in such cases, the patient may expel what have been described by Dr. Montgomery as "solid substances of a fibrous appearance externally, and varying in size, from that of a fig to that of an almond, which they resemble in form, being in fact moulded to the shape of the uterine cavity. These substances, when cut into, are found to consist . . . of layers of coagulum, between which there is interposed a thin, membranous-looking stratum of lymph; and others, again, are a combination of coagulated blood with the membranous production first described, around which blood is effused and condensed before its expulsion from the uterus, in which case, when a section is made through the centre of the mass, it is found to consist of an outer coat of condensed coagulum lined by the membrane, the smooth surface of which is thus laid open" (pp. 271-2).

Leucorrhœa, as is well-known, is an almost constant accompaniment of uterine neuralgia; and the explanations which I have already given will have fully prepared my readers for the announcement that this malady is really of nervous origin, and that it consists in nothing more than an abnormal augmentation of a normal process, viz., the secretion of mucus which, whatever be its quantity, is eliminated from the blood by the mucous gland-cells only when they are stimulated to action by nerve currents passing along nerve-fibres, generally, at all events, of cerebro-spinal origin, fibres directly innervating the gland cells, and conferring upon them their peculiar power, while attracting blood to themselves, of extracting from it the fluid they secrete. The function of the sympathetic in relation to the gland is, I hold, merely vasomotor or, through its action on the arteries distributed to the glands, regulative of their blood supply. Now, in reviewing the symptoms already mentioned as associated with uterine neuralgia, I have shown that they are all referrible to hyperæmia, and therefore, exalted function of the nervous centres governing the womb; and if the mucous glands work only by the agency of the nervous force and mechanism just described, it is evident that the vigour with which they work will be proportionate to the energy conveyed to them, and that if the nervous centres governing them are hyperæmic—as, in cases of uterine neuralgia, I have shown them to be—it is obvious that leucorrhœa is simply a result and expression of such hyperæmia. I am aware that this doctrine is revolutionary of the prevailing ideas and practices of the profession in respect to leucorrhœa, and therefore that powerful evidence will be necessary in order to substantiate it; this, however, I am able to give, in the shape of a considerable number of cases proving that by exerting a sedative influence on the nervous centres related to the reproductive organs leucorrhœa is rapidly cured. I may add here that though my explanation of the *mode of action* of the nervous system in producing leucorrhœa may be new, the conception that the nervous system does produce it is not

---

(*a*) "An Exposition of the Signs and Symptoms of Pregnancy, with some other papers connected with Midwifery." By W. F. Montgomery, M.D. Second edition. Pp. 272-3.

new; it was expressed by Mr. Teale in 1829 (*a*), by Dr. and Mr. Griffin in 1844 (*b*), and subsequently by several pathologists; in his "Clinical Lectures," published in 1856, by Professor Bedford, he says,—"The interesting tables of Marc D'Espine show very conclusively that a discharge of mucus from the vagina, more or less profuse, will be occasionally observed, constituting a species of leucorrhœa dependant exclusively, as has been proved, on a peculiar irritation of the uterine nerves. . . . This important principle in uterine pathology has been fully discussed by Reclaim, Mitchel, Malgaine, Beau, and others; and assuming it as a basis for their therapeutics . . . they have treated, and successfully, too, this particular form of uterine catarrh consistently, viz.: through revulsive agents applied to the lower portion of the spine, such as blisters, cauterisation with the red-hot iron, &c." Professor Bedford prefers "the insertion of a nitric acid issue on the side of the lumbar vertebræ," because, among other reasons, it "is more positive in its action than blisters." The fact of the notably slow spread of the doctrine of the nervous origin of leucorrhœa is, perhaps, partly accounted for by the unwillingness of patients to submit to these questionable and very uncomfortable remedies, and partly, I would fain hope by the unwillingness of physicians to prescribe them.

Another collateral, very common, and often very distressing, symptom of uterine neuralgia is *prolapsus uteri*, and many patients complain especially of bearing-down pains. Dr. Handfield Jones begins his chapter on "Uterine Neuroses" with these words,—"The uterus seems to come in for a fair share of neurotic disorder. This, indeed, might be expected, not only from its functional importance, and its extensive sympathetic connections, *but from the marked depression of nervous power with which its monthly evacuation seems to be almost constantly associated*" (*c*). And, again, in his account of the case, which he numbers 153, in which the patient complained of "violent pain at the lower part of abdomen and bearing down," he remarks,—"In this case the affection of the sensory nerves was complicated with paresis of the vaso-motor." It will be seen that this physician's view of the state of the nervous power, related to the womb during the menstrual period, is diametrically opposed to that which I have expounded, and I must now add that though, at first sight, his explanation of the "bearing-down" in the case just mentioned—viz., that it was due to nervous paresis—seems thoroughly reasonable, it is, in fact, as I am prepared to prove, erroneous, and the very opposite of the truth. Bearing-down or prolapsus of the womb in cases of uterine neuralgia, and, indeed, in a large number of other cases, is immediately due to extreme contraction of the arteries supplying blood to the uterine ligaments, as well as to the uterus itself. This contraction shuts off the blood to such an extent as to produce marked anæmia, and consequent feebleness of those ligaments which, becoming relaxed, permit of the prolapsus in question. This hypothesis I must also leave in this place without proof, begging my readers to suspend their judgment in the matter until they have read the evidence which I hope soon to publish, in the shape of a record of cases demonstrating the truth of my statement; meanwhile, I may say here that I have repeatedly proved that, by increasing the circulation of blood in the pelvic viscera, the prolapsus in question disappears. Now, if the explanation just given be correct; if, in fact, the immediate cause of the prolapsus be undue contraction of the arteries of the womb and its appendages; and if, as we know, such contraction is itself caused by preternatural energy of the vaso-motor nerves distributed to those arteries, it is certain that the real cause of this prolapsus is hyperæmia—instead of anæmia, and consequent paresis—of the vaso-motor nerve centres in question.

There are a few other symptoms occasionally presenting themselves along with uterine neuralgia which I shall be able to dispose of in a few words. The *tenderness of the vagina and intolerance of coition* occasionally complained of are obviously referrible to the condition of the nervous centres already insisted on. When inflammatory symptoms are present the tenderness in question is likely to be most acute; but intense hyperæsthesia, of course referrible to hyperæmia of the sensory nerve-centres only, is quite sufficient to produce both intolerable sensitiveness of the vaginal walls and that vehement spasm of the same, to which Dr. Marion Sims has especially called the attention of the profession under the name of vaginismus. The *frequent micturition* and *pale and abundant urine*, also often associated with uterine neuralgia, are, as I am prepared to prove, referrible to the same cause as the symptoms discussed above. *Sickness*, *nausea*, and *capricious enfeebled appetite*, as well as *constipation* and *flatulence* may also be shown to originate in hyperæmic disorder of the spinal cord, and collateral sympathetic ganglia; and, whatever may be the remote cause, the proximate cause of the *shivering*, *flushing*, and *feverish nights* frequently complained of by sufferers from "irritable uterus" or uterine neuralgia consists not less certainly in alternate hyperæmia and anæmia (the latter a result of re-action in the circulation) of those nervous centres.

(*To be continued.*)

MEDICAL SOCIETY OF LONDON.

Monday, December 18th, 1871.

Dr. Andrew Clark, President in the Chair.

Mr. Thomas Bryant made a communication and exhibited

DRAWINGS ILLUSTRATIVE OF THE PROCESS OF CELL GROWTH IN THE OPERATION OF SKIN-GRAFTING.

M. Reverdin when he made his communication on *this* important subject of skin-grafting, propounded the following questions:—

I. Was the skin-graft an exciter of skin action?

II. Or were the cells themselves of the graft proliferated?

Mr. Bryant contended that the grafts grew. The skin is *prolonged* from the graft, the borders also of the wound throw out growths. A white man was suffering from a large ulcer on the leg, a negro being in the hospital at the time, a small portion of his skin was transplanted, the ulcer decreased in size, and a piece of black skin the size of a grain of wheat increased very much in size. A little piece of black skin, which was well *isolated*, has assimilated to the white skin somewhat in appearance having become paler in colour. It was an interesting question whether the black skin would become paler or white. The cicatrix in the black man was darker than the surrounding skin. The author thought the practice of transplanting from one person to another was objectionable, it was better to take the grafts from the patient, even in children. Some skin taken from an amputated leg was placed in warm water and used for grafting. The grafts so obtained lived, but little more, they did not assimilate with the tissues round, but remained mere grafts. It might be possible to inoculate cancer or syphilis. In a case of *extroversion* of the bladder, a skin-graft lived, but nothing more, the mucous membrane did not become skin. An ingenious instrument for taking grafts was shown.

Dr. Ogle (of Derby), read a paper on

PREVENTIVE MEDICINE OR MEDICAL REFORM: NOT PARLIAMENTARY, BUT PARTICULAR AND INDIVIDUAL.

Very much has already been done by Parliamentary Reform, but the time has come when some considerable modifications of individual action in our dealing with the public is demanded, the author had been physician to a London Dispensary, and found the system liable to many abuses, social, moral, and medical, he was also Hon. Sec. to a committee of inquiry, similar to the one that has just been sitting. The working of provident dispensaries did not satisfy us, but we discovered that the social principle of providence, has an exact counterpart in the medical principle of prevention. Prevention is the highest function of our profession. Mr. Haviland's maps show at a glance where the mortality in England is above the average. The Registrar-general's reports show what an immense number of preventible deaths take place yearly. A commercial traveller had sent for him to see a child suffering from scarlet fever, because he took his guinea and did not call again until sent for, the wife also took a fever. A second child, slightly ill with it, was taken out in a cold east wind, was chilled, became dropsical and died. This condition of things might be prevented. An errand boy but recently recovered from scarlet fever infected *this* family. Phthisis is one condition tending to disease, might be healed easily and much harm prevented. He then submitted the following arrangement:—1. So much per annum for all ordinary work, the amount being left open, to differ according to circumstances, and that II., charges per visit shall be restricted altogether to extraordinary acts of service. Physic should, whenever possible, be supplied by druggists, if not it must be charged for separately. He proposed further, that the *term* ordinary should include all visits for which request has been made before a certain hour, varying for different families according to circumstances. It might also be understood, that the doctor in answer to such application should be at liberty to call or even to send a substitute at any time in the course of the day most convenient to himself. On the other hand "extraordinary visits should be night visits, but of these only such as are specially requested." Sunday visits specially requested, and visits in obedience to messages to come "immediately" or at some particular time named by the patient. The doctor would become a health officer, and would enjoy a freedom to do his duty, which at present he does not possess, and the interests of the doctor would be identical with those of the patient. The doctor would be emancipated from all the trading accessories of the profession which are now so galling; he would have no pecuniary interest in the amount of physic consumed, and would have no trade stimulus to pay many visits. His domestic comfort would be much increased, as he would know at breakfast time what his day's work was. When a summons to come "immediately" was sent, he would be sure that it was not a mere whim of some inconsiderate or fanciful patient. Whims and fancies would be reduced to a minimum. Advice given to a young physician twenty years ago who was desirous of becoming a specialist was, if you wish to get on you must throw open your house and give advice gratis to all comers, and you must write a work. In the present day the columns of the *Times* set forth any number of books on special diseases, the public is often unable to distinguish between a doctor and a mere quack. If the family doctor occupied the position thus assigned to him, the tendency would be to encourage a greater number of first-class men to devote themselves to special practice. Consultation practice in the country is not what it ought to be, and it is a reproach to our profession, that consultations should be so seldom held, and that there should be so much mystery in holding them. In any other walk of life consultation with a friend is the rule, independent action the exception. One man will not meet another because he is his junior. A physician will not meet a general practitioner because it is *infra dig.* A general practitioner will not meet a physician in a question of surgery and so forth. The two doctors meet first to talk the case over, instead of taking special care to avoid a bias being given. It is not to be wondered at, that the patient takes the train to London, and unknown to the family doctor consults some one, and gets an independent opinion. The patient ought to have liberty to call in whom he pleases, and special provision is to be made so that the second opinion shall be formed independently before the consultation proper is commenced. As to difference of opinion, they are not marks of ignorance but the contrary. The bearing of the preventive plan among the poor was then considered. The fundamental error of Mr. Smith, the philanthropist, who invented provident dispensaries was, that he adopted a uniform and, therefore, a minimum scale of payment. Restriction in this necessitated restrictions elsewhere and other interferences, notably, that not more than a certain number of medical men shall be upon the staff, a manifest injustice to those who are excluded, and a withdrawal to the same extent from the patients of the benefit of competition; then there must be of necessity a committee of inspection to exclude members who ought to pay more than a penny a week, a duty so invidious, that practically it cannot be carried out. But the strongest of all the objections is, that these institution never aimed at, and therefore could never attain, a higher standard than that of mediocrity. Appeals to the public for subscription are wrong in principle.

A long and careful discussion followed the reading of this paper, in which the President, Dr. Routh, Dr. Crisp, Dr. Gibbon, Dr. Ford Anderson, Dr. Brunton, Dr. Symes Thompson, and Mr. Davy took part.

◆

DUBLIN OBSTETRICAL SOCIETY.

The second meeting of the Society for the present Session was held on Saturday evening (16th December), in the College of Physicians. **Dr. Kidd**, President of the Society, in the chair.

Dr. A. H. **Ringland** read a paper

ON THE OPERATION OF TRANSFUSION.

He gave an interesting sketch of the history of the operation and the controversies to which it had given use, and attributed much of the success which transfusion had had in the present day, to the practical ability of Dr. Blundel, who revived the operation after it had fallen into disuse, and proved by experiment that blood could be received into a vessel and passed through a syringe into the veins of another individual without losing any of its beneficial effect. Having detailed the subsequent progress of transfusion and quoted Graily Hewitt, Routh, Soden, and Brown-Séquard as authors on the subject. Dr. Ringland said that to render the operation safe, many instruments had been invented, but that for mechanical completeness, simplicity and safety, the apparatus recently invented by Dr. Robert McDonnell, surpassed all others. This apparatus had the advantage of dispensing with the use of the syringe so ill adapted to emergencies, a glass pipette being used instead of a syringe, and the blood going in by gravitation or by blowing gently into the pipette. Dr. Ringland then described a case in which the operation of transfusion had been recently performed. He was called to attend a woman in her tenth labour; and on his arrival found her in a state of extreme exhaustion from profuse hæmorrhage. The hæmorrhage was arrested, but in spite of the use of brandy, &c., she could not be roused from her prostrate condition. It was therefore determined to try transfusion. Dr. McDonnell's aid was sought for, and he performed the operation, the details of which, Dr. Ringland described. Unfortunately, the operation did not succeed, several ounces of defibrinated blood had been transfused when a deep gasping sound was heard, and the patient was dead—the inference drawn by Dr. Ringland being that they should be careful in certain cases of uterine hæmorrhage not to delay the operation until the patient's powers of reaction were paralysed:

At the conclusion of Dr. A. H. Ringland's communication, **Dr. Ringland** read a paper describing the particulars of another case of transfusion. On the 3rd of October he was sent for to see a lady, 23 years of age, who had been delivered of her third child. There had been violent flooding on the two previous occurencies, and on the completion of the third labour profuse hæmorrhage set in. By the use of perchloride of iron the bleeding was arrested, and brandy and ergot were administered with the effect of improving the circulation and causing contraction of the uterus. Nevertheless the pulse indicated great prostration; it was 120, and compressible, and at times not distinguishable. She was restless, with laboured respiration, and fatal issue was all but impending. Dr. Johnston who saw her with him, agreed that transfusion should be tried, and Dr. Robert McDonnell was sent for. It was twelve o'clock at night when the operation was proceeded with, the pulse at that time being wanting at the dorsum of the foot and at the wrist and arm, and the second sound of the heart being inaudible. An incision was made in the skin over the cephalic vein, and an acupressure needle passed under it to enable them to command the vessel. The operation occupied a considerable time, and great pressure had to be used to push in the fluid. Scarcely more than three or four ounces of defibrinated blood were transfused when a pulse was felt, and when not less than twelve ounces in all were introduced, the patient rallied considerably.

The subsequent treatment was then described: Opium was largely given to the extent of a pill containing one grain each hour. On the third day after the operation there was a slight hardness of the vein observed, but this yielded to the application of nitrate of silver. The lady recovered perfectly, and in Dr. Ringland's opinion had been snatched from death by the operation of transfusion, when all other means of saving her life had been adopted and failed.

The **President** said,—He had not himself witnessed any case of transfusion, but he had been on many occasions prepared to have it done, and had watched the cases carefully with Dr. M'Donnell's assistance, in order to perform the operation if necessary, and they had always, except in one case, postponed the proceeding. It is important to watch the right time to perform the operation, and he must say the case recorded by Dr. A. H. Ringland shows the importance of not delaying it too long. The first case in which he contemplated transfusion was a very sad one. It was that of a lady in the suburbs of Dublin, who had a miscarriage. When he saw her she had been bleeding from ten in the morning until four in the afternoon. He at once succeeded in removing the placenta and membranes, and there was no further bleeding, but the progress of the case was downward; she gradually became lower and lower. He sought the assistance of Dr. Beatty, and, when he arrived, at his suggestion, Dr. Robert M'Donnell, and the means of performing transfusion, were sent for. Everything was prepared, the husband afforded the blood, it was strained, and everything was ready, but, as they were about to open a vein in the arm, she breathed her last, and the case made a deep impression on his mind. The two successful cases now recorded by Dr. Beatty and Dr. Ringland should make us resort to the operation at an earlier period.

A remarkable paper appears in the *Lancet* of this day, giving an account of three cases of transfusion, two successful and one unsuccessful. There was this extraordinary feature about the unsuccessful case, that the defibrinated blood used had been drawn out the night before, and preserved for fourteen hours before being injected into the veins, but that does not appear to have had any influence on the result of the case. The operation was resorted to in that instance because of the exhaustion produced by a gastric ulcer. The other two cases were cases of poisoning, one by phosphorus and the other by carbolic acid, and in these cases a quantity of blood was withdrawn equal to the quantity injected. The cases are very interesting, but they are recorded in such a manner that perhaps implicit reliance could not be placed on them.

Dr. Robert M'Donnell said there were some operations, such as those for the removal of tumours and for aneurisms, &c., which could not be practised on the dead subject. There were others, of which transfusion was one, which could be thus practised; and that being so, it was inexcusable for any young surgeon not to avail himself of his opportunities to make himself familiar with the details of an operation which he might afterwards find necessary for the preservation of life. This was essentially an operation of detail. In the first instance, perfect cleanliness was indispensable. All the instruments, the tubing, the pipette, should be perfectly clean; the bowl in which the blood was received should be scalded with hot water, and the muslin used in straining the blood should be scalded also. In the second place, the only really difficult part of the operation when it came to be performed was the opening of the vein in the person into whom the blood was to be transfused. It was like taking up a vein in the dead body. There was this only difference between the dead and the living bodies—that in the latter, owing to the cold air getting at the vein, its muscular fibres contract, and it becomes very small. Hence the importance of passing a needle under it, so that one might always be able to find it when necessary. He believed that in both the cases that were detailed that evening the apparent difficulty found in putting in the blood arose from their natural anxiety to see it flow in quickly. You think the blood is not going in, when in reality it is going in, but very slowly. He had never found any instance, when practising on the dead subject, in which the weight of the blood was not of itself sufficient to make the blood run in without difficulty. The nozzle which had been described by him in the *Dublin Quarterly Journal* was an important part of the instrument.

It is of great importance to have a canula, with a probe point, and the eyelet hole at the side, not at the end. The probe point was best suited for entering a small opening. They could easily make sure that all air was expelled before they put it in, and if during the progress of the operation a bubble of air was observed, it was possible to withdraw it, and allow the air to escape without any serious interruption of the operation. There was another advantage in an apparatus of the kind exhibited, well illustrated in the case detailed by Dr. Ringland. There was some delay experienced in getting at the vein in the woman's arm when all was ready for making the injection. In such a case it was only necessary to place the nozzle in the top of the tube, and the pipette could then be placed in a can of hot water, and allowed to remain there as long as the operator wished. It was evident that this was a great advantage, inasmuch as everything could be got ready for use without undue haste, and the operation could be carefully and deliberately performed without fear of the blood getting cold. He believed this operation was capable of being applied to a large number of cases besides those with which the members of that Society were so familiar in obstetric practice.

He would mention an instance of a surgical case in which transfusion might have been applied with advantage. A man whose limb was torn off had come a long way from the country, and arrived at hospital exhausted from loss of blood; nevertheless it was deemed advisable to amputate, and he died within a day or two after the operation, but seemed to be run down by that kind of secondary fever which follows exhaustion from extensive hæmorrhage. Now he should think in such a case of saving the patient's own blood, unavoidably lost at the operation, and having it defibrinized, and then after the operation giving him back his own blood, thus giving him promptly what is equivalent to a good meal of nutriment to start him on his way to recovery. He belived the most important thing connected with this operation was establishing the desirability of introducing defibrinated blood. In former times it was held that fibrin was an important nutritive part of the blood; it was considered that the blood was deprived of its most essential element when the fibrin was taken away; but physiologists had now come to the conclusion that fibrin, instead of being an all-important nutritive element, was rather an excrementitious matter which was given to the blood as it returned from the tissues after doing its work, and that it was an advantage to get rid of it. His (Dr. M'Donnell's) physiological experiments had proved this to be the case. He observed this when repeating the experiments of Dr. Brown-Séquard on limbs of animals removed from the body, on animals deprived of the head, and on the head removed from the body, whereby the vital phenomena were reproduced by keeping up an artificial circulation. He placed on a tray the head of a dog which had been severed from the body, and with a double action syringe injected the oxygenated and defibrinated blood of a sheep into the veins, producing artificial circulation through the brain of the decapitated dog. The vital phenomena were produced—the jaw opened, the tongue was protruded, the eye moved, but the blood which flowed out through the veins coagulated. Defibrinated blood was thrown in, but there was carried out, taken away from the tissues, fibrin that coagulated, thus proving that the fibrin found in the blood is an excrementitious matter carried away from the tissues. This remarkable fact, coupled with what they knew of the liver and kidneys, which were blood-purifying organs, namely, that the blood in the hepatic vessels and in the emulgent veins after leaving the kidneys did not coagulate, left little doubt that the fibrin was not a nutritive element of the blood. Hence, physiologically speaking, the defibrinated blood was better for the patient. He need not say it was important also in a surgical point of view. The risk of trying to inject blood not defibrinated was very great, and he was of opinion that the deaths which occurred several days after transfusion occurred from embolism. He said then that, physiologically, the defibrination of the blood made it better for the patient, and surgically it disarmed the operation of most of its dangers and its risks. With regard to the difficulty experienced in Dr. Ringland's case in getting the blood in, he was inclined to think that in all these cases it arose from their being rather precipitate, and thinking that the blood should go in faster than it really should. He had contrived a simple apparatus, by which a good deal more force could be put on, as in Bellina's apparatus by an Indian-rubber bottle; but at the same time he did not recommend it. It was important that the blood should not flow in too quickly, and he believed that gravitation alone was sufficient to get it in—at least gravitation aided by the pressure of the mouth. Care should be taken not to have the blood too hot. The operator should be provided with a thermometer in every case, otherwise he ran the risk of producing coagulation of the albumen. The blood should be heated from 100° to 105°, at which there was no risk of coagulation, and this temperature could be easily maintained. There was one interesting point to which before sitting down he wished to allude. Some remarkable experiments, reported in the proceedings of the Royal Society, had been performed with the view of proving whether the breeding of rabbits could be altered by the transfusion of the blood of one kind into the veins of another. The experimenter transfused the blood of the lop-eared rabbits into ordinary rabbits, and bred from the latter to try whether they would give birth to a lop-eared progeny. The result, however, was negative. The transfusion did not bring the spermatic animalcules into harmony with the blood flowing through the veins of the animal. These experiments were brought forward in opposition to the theory of pangenesis of Darwin, and might at least serve to allay the fears patients had sometimes entertained lest they might partake of the peculiar character of the person whose blood was thrown into them. It was desirable of course that the blood should be taken from a healthy person, and, above all, they must take care that there was no syphilitic taint in the blood used.

Dr. Beatty had listened with great pleasure and instruction to the papers which had been read by Dr. Ringland and Dr. A. Ringland, and he congratulated the former on the successful issue of his case, and the latter on the diligence and skill which he had brought forward all the accumulated knowledge on the subject, and the very lucid manner in which he had described the operation. It was rather a remarkable thing, and one on which they were justified in congratulating themselves, that this very rare operation should now have been three times performed in a short space of time, and twice successfully in this city.

Dr. Johnston said that having seen fearful results from loss of blood after childbirth, he must corroborate Dr. Beatty's opinion that they should not wait too long to see the effects of the hæmorrhage, but at the proper time, when it was seen that all ordinary means had failed, they should interfere in this method, which Dr. R. M'Donnell had rendered so easy for their adoption. A short time since he was called to see a case of hæmorrhage in the fifth month. It was a case of abortion, and, he thought, owing to some oversight on the part of the physician, the whole of the membranes were not removed until a month afterwards, when severe hæmorrhage took place. Such was the state of exhaustion that when he (Dr. Johnston) arrived, he found the woman quite pulseless. He found part of the placenta remaining, which he removed, and, by the injection of perchloride of iron of the usual strength, he succeeded in arresting the hæmorrhage, and then by stimulating the patient by enemata of beef-tea, wine, and opium, he brought back the pulse. If, however, he had failed with the remedies he applied, he would have sought the aid of Dr. M'Donnell, and performed the operation of transfusion. Although he had been successful in the case referred to, he would not advise any gentleman to depend too much on perchloride of iron or any astringent mixture for arresting hæmorrhage.

Dr. Denham must express the intense satisfaction he felt in listening to the papers of that evening, and the discussion which they had elicited. He looked at it as the most important meeting the Society had ever held. He had listened with great interest to the details of Dr. Ringland's case, and it passed through his mind at first, as it probably did the minds of other members of the Society, that they had seen cases apparently quite as far gone recover. That idea, however, was largely dissipated when he came to hear the details and the result of the treatment after the operation. When he found the patient was able and required to take a grain of opium every hour for sixty or seventy hours, he concluded that the vital powers must have been at a low ebb. In that case the system was in the condition of a patient dying from cholera. Such a quantity of opium could not be introduced into a person in good health, and doubtless in this case a large portion of it was never absorbed, but passed down the alimentary canal without producing any effect on the system. The large quantity which had been administered, however, showed that the operation was called for. Every practitioner of midwifery, on looking back over his practice, must recall to his mind instances of valuable lives that might have been saved if they had been familiar with the operation of transfusion. He would mention one, a case which had made a great impression on him, of a lady who had bled to death simply from the application of six leeches. She was a person of delicate constitution, was confined safely, and went on well for some days. On the occasion of the milk fever there was some tenderness over the uterine region, and he ordered the leeches to be applied. The nurse ignorantly encouraged the bleeding by poultices. Another practitioner, not familiar with these cases, was called in, and he attempted unsuccessfully to stop the bleeding. He (Dr. Denham) was then sent for, after the bleeding had gone on for several hours. However he succeeded in commanding the hæmorrhage from every vessel. It happened to be the morning of the funeral of his lamented and esteemed friend, Dr. Mayne, and, being anxious to attend it, he left a friend with the patient during his absence, and on his return from the funeral the patient was dead. The bleeding had been completely stopped, but the vital powers going down, the woman died. He had not the slightest doubt that her life would have been saved if they had been familiar at that time with the operation.

Dr. Churchill said all present must have listened with great interest and instruction to the points recorded in the papers themselves, and to Dr. M'Donnell's very instructive observations on the operation. He (Dr. Churchill) remembered Blundel's operation, and the operation fell through then from the accidents that occurred; and he had a strong suspicion that a good many of them might have resulted from the fibrina in the blood. The most important point was the defibrination of the blood, for then there was no chance of embolism or other accident occurring. Blundell, he remembered, laid great stress on the blood being introduced very slowly. He set some one to watch the eye of the patient, and the moment he saw a flicker of the eyelid he stopped the introduction of blood. If the blood went in by gravitation, as Dr. M'Donnell said, it could not go in too fast. As to the free use of opium after large hæmorrhage, he thought three-fourths of it had no medical effect. Dr. Haughton examined some time ago the body of a person who died of cholera, and who had got more than twenty pills with a grain of opium in each, and he found all the pills in the stomach. He had heard of cases in which the effect of opium on the heart of the patient in cases of hæmorrhage was injurious, death having been caused in some instances. He thought, therefore, very great caution should be exercised in giving opium in cases of hæmorrhage, and he confessed he should be afraid of giving it to anything like the extent stated by Dr. Ringland.

Dr. Nuttall said the apparatus introduced by Dr. M'Donnell was so simple that any man with ordinary hands could use it, and it rendered an operation of great importance comparatively easy and safe. Some twenty years ago he tried the effect of injecting warm water, with salt and whiskey, into the veins of persons in collapse from cholera, and they were temporarily relieved; could sit up in bed and express themselves as being better than they were previously. Looking at this fact, it seemed to him that in cases where there might be a difficulty in getting blood, relief might be given in this way, with warm water, a little salt, and a small quantity of spirits. The object of using salt was, that it had a tendency to prevent coagulation of the blood.

Dr. Byrne also bore testimony to the great value of the instrument which Dr. M'Donnell had placed in the hands of the profession, and he had not the slightest doubt that when it came to be more generally known, it would be the means of saving many lives. These cases of hæmorrhage after delivery were often most formidable and rapid in their effects; and he could easily conceive a case where the transfusion of eight, ten, or fifteen ounces of blood, would save the patient's life.

In reply to Mr. F. T. Porter,

Dr. M'Donnell said the only surgical case in which he had performed the operation of transfusion, was one of tetanus. It did not exercise any control over the complaint, but after the transfusion the patient was relieved from the sensations of hunger and thirst, which she had previously felt very acutely, proving that the sensation of hunger which was transferred to the stomach, arose from the want of nutriment to the system generally. The patient was continually saying, through her clenched teeth, that she was dying of hunger and thirst; but an hour after the operation she was relieved from these sensations.

Dr. Ringland thanked the meeting for the manner in which his paper had been received. The subject all admitted to be one of great interest, and if his paper had produced no other benefit than eliciting the observations which had been made that evening, he thought he had done good to the Society. Dr. Denham said that it had struck him and others present that very probably the case might have recovered without any transfusion whatever, but that he was disabused of this notion when the subsequent details of the case were stated. He (Dr. Ringland) could only say in reply that it was the unanimous voice of Dr. Johnston, Dr. M'Donnell, and himself, that the time had come when nothing but the operation could save the patient.

ARMY MEDICAL SERVICE.

There are few things in the duties of medical journalism more disheartening than the consciousness that great institutions like the Public Services may be full of men in a state of discontent, justified alike by their past history, their anxiety to deserve well of the country and the prospect that the future holds in store. We all know how slow is promotion—how swift old age and death. Those who have given up the best portion of their lives to their country, too often feel that they would have done better in any other career, and yet it is too late to change. What can they do but go on in the hope of better days, when as they say they are fit for nothing else.

We have often urged the claims of our brethren on those in power, and challenged the verdict of public opinion as to their services. Even last week, when speaking of the honours due to medical men, and which the country is prepared to seize an opportunity of paying, we pointed out that our brethren in the public services ought not to be passed over. Further we repeat that they form a noble part of the great profession, and we would once more urge that their just claims be recognised. Promotion and other honours are valued by medical as well as combatant officers, and while all is at a dead-lock, the service is discontented. Men who would glady be employed are eating out their hearts in sadness and vexation, as they see no honours distributed and no promotion going on.

Writing on this subject, the *United Service Gazette* considers that the state of things in the Army Medical Department is one that calls for the immediate attention of the Minister for War. There are eight or nine inspectors-general all on full pay, and giving no indication of any intention to retire and make room for their juniors. Formerly these officers had a five years' tenure of active employment, the same as other members of the staff, but of late years this limitation seems to have been completely ignored, and the inspectors-general hold on, making the first and greatest block in the way of promotion. The remedy for this is simple enough: let each inspector-general who has had five years' tenure of his appointment retire, as is the custom with other staff officers, a custom which we believe is now to be stringently enforced in the major portion of the other branches of the military service.

The deputy inspectors-general, about twenty-four in number, also require a revision of their grade. By the Royal Warrant of October, 1858, it was ordered that these officers should, as well as the inspectors, retire at sixty-five years of age. But as a matter of fact, some still remain on active service whose ages exceed that limitation. An examination of the *Army List* would not disclose this fact, but the manner in which the Royal Warrant is evaded is by taking the official instead of the real age of the officer.

The surgeons-major number more than sixty. Of that number at least twenty could now retire at their maximum of half-pay, viz., £1 per diem. They still, however, hang on for promotion, which under the present constitution of the department they can never obtain within the limit of their ages. And it is to be feared that unless some compulsion be used, they will continue to the end of the chapter, forming a third and greater block to promotion than either the inspectors or deputy inspectors-general. The surgeons come next, and we believe that in their case a great impetus and inducement to retire would be afforded by the simple expedient of allowing them to go at their own option as soon as they had obtained their surgeon-majority, on the same terms as they would have been entitled to if retired by a medical board. One thing is certain, and that is, that something must be done, and done quickly, if we do not wish the Army Medical Department to languish and become effete under a system of promotion which is known to be the slowest throughout the whole of Her Majesty's military service.

◆

Notes on Current Topics.

The New Hotel Dieu.

The physicians and surgeons of the Parisian hospitals met together last week to hear the report of a commission which had been appointed to view the new Hotel Dieu, and to examine its hygienic condition. The commission was composed of Messrs. Hardy, Broca, Marjolin, Giraldes, Heraud, Lallier, Trèlat, Vidal, and Lorain. Some of the proposals submitted suggested that the hospital should be retained for the special purpose of skin diseases, eye diseases, &c., to the exclusion of fevers, wounded patients, and lying-in women.

Others proposed to keep standing a part of the building, and reduce one-half the number of beds; while others demanded the total demolition of the building, on the ground that it was altogether unfit for the purpose for which it was intended.

After discussion of these various proposals, the conclusion unanimously arrived at was as follows :—

"The Hotel Dieu, as it has been constructed, does not fulfil the requisite conditions for a hospital conformable to our present knowledge of hygenic science."

An Hospital Sunday for Dublin.

We derive much satisfaction in hearing that a movement has been set on foot in Dublin by Dr. Eames for the establishment of an "Hospital Sunday," which has been attended with so much benefit to the charitable institutions of Birmingham and Liverpool. The following circular was issued by Dr. Eames, and we understand that the acquiescence of all the hospitals named in it is assured, with one exception.

> Dear Sir,—The aid which your hospital and others receive from charity sermons being spasmodic and uncertain, it seems well that there should be some more reliable means of obtaining the support for hospital funds now derivable from collections made in churches. The formation of what is termed an Hospital Sunday in this city, as has been already done in various towns in England, would afford a permanent source of income to those hospitals now receiving occasional assistance. The institutions which it is proposed to include in this scheme are :—The Hospital for Incurables, the Convalescent Home, the City of Dublin Hospital, Sir Patrick's Dun's Hospital, the Meath Hospital, the Adelaide Hospital, and Mercer's Hospital. Already a very considerable number of the clergy of the city and neighbourhood have declared themselves most favourably disposed towards this arrangement, and have expressed their intention of adopting it.
>
> Will you kindly lay this matter before the governors of your hospital, and inform me whether or not they accede to this proposal.—I am, dear sir, faithfully yours, Henry Eames.

We anticipate that the co-operation of the hospitals will be unanimous, and we are strongly of opinion that any institution standing aloof will be pursuing a mistaken policy. Setting aside the obvious liberality of such co-operation, it seems to us more than likely that the dividend of each institution will be, under the "Sunday" system, more than any one institution now receives from charity sermons.

Adulterated Bread, and Analytical Chemists.

The *Australian Medical Gazette* says that the value of the evidence of the analytical chemists who had been recently examined as witnesses in a number of cases in which bakers had been proceeded against for adulterating bread with alum, was subjected to a crucial test in the district police court.

To determine the reliability of the evidence of the analytical experts, one pound of pure flour mixed with a certain proportion of alum was given to each to analyse. The alum known as ammonia-alum was the kind mixed with the flour. Three chemists—two not having completed their examinations—gave the results of their analyses. The issue clearly shows how very little reliance, in this instance at least, can be placed on the testimony of chemical experts. Only one out of the three analyses approached correctness. The following is the substance of the evidence :—

William Johnson, the Government analytical chemist, into whose sample 20 grains had been put, stated that he analysed the flour, and found alum to the amount of 4 grains to the pound.

Sydney Gibbons, analytical chemist, into whose sample 10 grains had been put, said he found a proportion of 21½ grains of alum to the 1lb. By another process 25½ grains of alum to the pound.

John William Hood, chemist, whose sample contained 15 grains to the pound, said he found alum present to the amount of 8 grains to the pound.

The late Professor Blyth, M.D.

The death of Dr. Blyth, Professor of Chemistry in the Queen's College of Cork, is a great public loss, as he was one of the ablest practical chemists of his time, and one of the most amiable members of society. Born in Jamaica and educated in Edinburgh, he passed several years on the continent; and, as the favourite pupil of Baron Liebig, was the translator of his works into English, and the able expounder of his opinions. His numerous old pupils will receive the announcement of his sudden death with the deepest regret, and to the present students his loss will be irreparable; for he had a tact and method of encouraging the slow, and assisting and forwarding the exertions of the intelligent that was peculiarly effective.

His public service as an agricultural chemist was most useful; and in the more difficult criminal cases his analyses were so searching and accurate, and his logical deductions from them were so able, as to carry conviction with them. On this account his decisions are frequently quoted as an authority.

The loss of such an able professor is the more to be regretted as the increasing number of students that are sent out every year qualified for high offices prove the usefulness of these admirable Irish colleges, and the difficulty there must be in procuring the services of such professors as the late Dr. Blyth.

Dr. Paget.

The resignation of Dr. Bond creates a vacancy in the Regius professorship of physic, and Dr. Paget, the able president of the General Medical Council, is spoken of as likely to succeed him. No one doubts his fitness. He would fitly occupy such a post. His name indeed is one that the Government should not omit in a distribution of honours to medical men, about which so much has been written by political as well as medical journals.

Ligature of the External Iliac Artery.

On the 10th of this month, in the operating theatre of Sir P. Dun's Hospital, Mr. Butcher ligatured the external iliac artery high up, for a large inguinal aneurism extending above Poupart's ligament. The patient is aged 68 and the case is going on most favourably.

Professor Hughes Bennett.

The whole Profession will learn with regret that Dr. Hughes Bennett is unable from ill-health to complete his usual course of lectures, and will probably take rest in the South of Europe. We sincerely hope that rest and change of air will speedily restore him to health, and that Edinburgh may long continue to have the privilege of numbering him among her teachers.

If honours were distributed to medical men as freely as they ought to be in an old monarchy like ours, Dr. Bennett would not be without recognition. He has done good service to Science, and even those who most differ from him in matters of opinion will heartily join in our wish for his speedy recovery.

The late Mrs. Browne's Money.

This lady, worth some £10,000 a-year, is said to have died intestate, and without near relations; so that her wealth will possibly revert to the Crown. It is hoped by many that should such be the case some of the money will be applied to the erection of swimming baths in the London parks, it being known that the deceased lady had intended to dower London with those useful hygienic appliances at her own cost.

What a pity the lady did not make a will, and thus ensure such a benevolent intention being fulfilled. It is to be hoped that the duty of making a will may become less frequently neglected.

Poisonous Effects of Belladonna applied Externally.

In the *Revue Médicale de Toulouse* M. Giscaro records, says the *Pharmaceutical Journal*, two cases in which persons had suffered from the poisonous effects of belladonna, applied externally. In one case, where a small patch of belladonna, the size of a two-franc piece, had been applied to the temple for a neuralgic pain, the patient eight hours afterwards showed decided symptoms of atropia poisoning, which lasted two hours. In the other case, where an excessive quantity of ointment had been used for a uterine affection, similar symptoms came on in one hour, but quickly disappeared with the removal of the dressing.

An Example for England.

Professors Stanislaus, Cannizzaro and Charles Maggiorani, of the University of Rome, and Prof. Louis Porta, of the University of Pavia, have been raised to the dignity of Senators.

The University of Dorpat.

Hitherto the chairs of this university were filled by professors who had gained a name in Germany; and this seat of learning, though under Russian dominion, was extremely prosperous, and maintained its Teutonic origin. But the system of Russianising annexed provinces has at last reached Dorpat. The University is being transferred to Wilna, where, of course, the Russian language will be exclusively used.

University College Hospital and the Cancer Hospital, London, have received bequests of £500 each, by the will of the late Emanuel Mocatta, Esq.

On the Geography of Disease.

Mr. Haviland will commence a course of six lectures on the Geographical Distribution of Disease in England and Wales, on Thursday evening, February 1st, at Eight p.m., in St. Thomas's Hospital. The subject of the two first lectures will be The Distribution of Fevers (Typhus, Typhoid, and Continued) in England and Wales, the Geography of General Health, Phthisis, Cancer, Scrofula, and Heart Disease will form the subjects of the remainder of the course.

On Saturday evening the gigantic marine aquarium at the Crystal Palace was publicly opened to a select number of persons, chiefly members of the press, with a short address by Professor Flowers, F.R.S., "On the formation and habits of some of the most familiar species of marine fishes."

After March 31st the entrance fee to the Medical Club will be raised to fifteen guineas, and the annual subscription to six guineas. Until then the entrance fee will be ten guineas, and the annual subscription five guineas, and for members abroad one guinea.

A competitive examination for the admission of assistant surgeons into the Royal Navy will take place at the University of London, Burlington gardens, on Monday, 12th February, 1872, and following days, at Ten o'clock. Candidates must present themselves at this department on Friday, 9th February, 1872.

Mr. Samuel, a Member of the Council of University College, London, has announced his intention to at once present the authorities with the munificent gift of £4,000 towards the further extension of the buildings. This gentleman has previously given donations to the amount of £3,600, with several smaller ones for various college purposes.

The Medical Society of the College of Physicians, Ireland, will meet in the College Hall, on Wednesday, 17th January, at eight o'clock. The following communications are set down for reading:—1. Dr. Hayden, "To exhibit and describe a Stethometer." 2. Dr. W. Malachi Burke, "Observations on the present epidemic in Small-pox." 3. Dr. Laffan, "Observations illustrative of the use of the Pneumatic Aspirator."

In an additional article on the Pharmaceutical aspect of the Medical Declaration respecting alcohol, the *Pharmaceutical Journal* says:—

"Will any of our readers (east or west, no matter) pause to consider how often they, or their assistants, are asked for 'pick-me-ups' by their male, and for that popular composition commonly known as 'red lavender' by their female clients? Have they any idea at all as to what proportion of gentian, lavender and other tinctures, of eau de cologne, chloral hydrate, and compound spirits of ammonia sold is taken for really legitimate and beneficial purposes? These are questions well worthy of consideration, and we believe that those of our readers, who consider them carefully in all their bearings, will come to the conclusion that the sale of these articles for the plain purpose of producing an artificial stimulus to mental or physical exertion has during the past few years, increased in a most marked degree, and to a most pernicious extent. We believe that chemists could, if required, give most valuable evidence on this point; for it is perfectly well known to all medical men practising in London that many of their upper and middle-class clients of the other sex, not daring to keep a brandy bottle in their closets, find nevertheless a convenient and (as they suppose) a safe substitute in the imbibition of small and oft-repeated doses of lavender tinctures, eau de cologne, etc. And it is as patent that our readers must know a great deal about the way in which these articles are obtained, and can form also a tolerably correct idea as to the rate of consumption."

THE Rev. Mr. Watson has been found guilty and condemned to death. An effort was made to prove him insane, and since the conviction other steps have been taken in this direction. Dr. Blandford, Dr. Maudsley, and others, have signed a certificate to the effect that they believe him to have been insane at the time of the committal of the crime.

WE have received Mr. Tweedie's Temperance Year-Book for the year 1872. The recent Medical Declaration respecting the use of wines and liquors is prominent in this volume. It contains a general review of the temperance movement during the last year, and gives much curious information. There are several articles amongst the "Scientific Facts for Temperance Advocates," to which we would call the attention of our readers. In 25,376 inquests in 1871, 316 verdicts were found for death through excessive drinking, against 322 in 1869 with a less number of inquests, viz., 24,709. Respecting the United Kingdom Temperance and General Provident Institution, it is said that the bonus in the Temperance Department contrasted favourably with that in the General Department, so that temperance is supposed to contribute to longevity. If so, our profession might be a little less busy.

Two children have just died at Huddersfield from the effects of a sleeping mixture. They had been restless and screaming, and their mother was advised to procure a sleeping medicine. She sent to Mr. Geo. Hall, a chemist at Kirkgate, for a quantity of opium and aniseed, which were to be simmered in water and a certain quantity administered to the children when unwell. No directions were given to the mother of the children by the messenger who brought the medicine, and about four o'clock on Saturday afternoon, the 24th ult., she simmered some, and administered about a dessert-spoonful to one of the children, who became very ill in the evening and died at half-past nine. She had also given some to the other child, who also became so ill on Sunday, that Mr. Goodall, of Lockwood, was called in, who prescribed for it. It died at 5 a.m. on Monday morning. It is reported that no directions were given to the mother of the children respecting the medicine, and that there was no label on the box containing the opium.

The *Spectator* has the following :—

The medical journals are priding themselves, not without justice, on the science and skill shown by the physicians of the Prince of Wales in pulling him through his imminent danger, and are dwelling on the patience with which the regular and well-known course of the disease's development was watched without any even momentary hesitation as to the treatment. This pride is perfectly natural and just; perhaps even they may be right in quoting, with a sort of triumph in the imaginative force of the expression, the words "of one of the two great clinical authorities to whose care the Prince was entrusted," that "it is not so much that a man has the fever as that he *is* the fever" (though we should have thought it could not be more correct than to say that "it is not so much that a man is in health as that he *is* health," which surely wouldn't be quite correct); but we do think the theoretic science and skill of the profession might have been more merciful to us in point of grand words. Why were we told, when the temperature of the Prince was gradually becoming lower, that "the process of the defervescence continued satisfactorily,"—when the pain above the hip-joint followed the fever, that it was one of "the sequelæ of typhoid," and that it was aggravated by "the long accubitus,"—*i.e.*, in plain English, the lying-down? And why does the profession so acutely enjoy imposing on us with big words that it tells us that in typhoid the fever-process "is a species of pathological paraboloid, which describes a curve for an average of twenty-eight days?" A paraboloid is a solid figure generated by the revolution of a parabola round its axis; now, what conceivable meaning can be expressed by saying that a fever-process is a solid figure at all? Still more that it is the special kind of solid figure caused by the revolution of a parabola, and most of all, that it is such a solid figure *as describes a curve for an average of twenty-eight days?* It is all very well for learned medical writers to practise upon the weak nerves of us laymen with their grand technical terms, but at least let them themselves understand the words they use, and not invent them *merely* to hurl them at and astonish us, as the *British Medical Journal* uses this unfortunate "pathological paraboloid" that is guilty of describing curves, as if it were a sort of moon, in a periodic time of twenty-eight days.

◆

SCOTLAND.

EDINBURGH.

A REQUISITION has been presented to the managers of the Royal Infirmary by 286 of the contributors, asking that a special meeting of the contributors be called to re-consider the motion of Professor Masson, which was carried at the meeting held on the 2nd, relative to the admission of lady students to the Royal Infirmary. The memorial states, that the motion was proposed without due notice, in the face of a protest by nearly one-half of the meeting, and that in its results it may prove prejudicial to the interests of the hospital. The managers have resolved to delay consideration of the memorial until after the adjourned meeting of contributors on the 15th. The requisition is signed by several ladies and by many of the most influential members of the court of contributors. The following resolution was adopted by the University Court at a meeting held on the 8th:—

> The University Court have had under consideration the letters of Miss Jex Blake and Miss Louisa Stephenson, of 21st November, 1871, and other relative documents laid before them, on behalf of the women who have been admitted, by the regulations of the Court of November 10, 1869, to study medicine in the University.
>
> In these papers it is stated that certain professors of the Faculty of Medicine have declined to give separate courses of instruction to women; and the Court are asked either—1. To extend, in the case of female students, the privilege granted, by ordinance of the Universities Commissioners, to lecturers, not being professors in a University, of qualifying for graduation by their lectures, which privilege is now restricted to four of the prescribed subjects of study; or 2. To authorise the appointment of special lecturers to give, in the University, qualifying courses of instruction in place of those professors who decline to do so; or, 3. To ordain that the professors se-

ferred to shall themselves give the necessary courses of instruction to women.

The second course suggested it is not in the power of the Court or other University authorities, singly or jointly, to adopt.

The third course was equally beyond the power of the Court. The Act of 1858 vests in the Court plenary powers to deal with any professor who shall fail to discharge his duties. But no professor can be compelled to give courses of instruction other than those which, by the use and wont of the University, it has been the duty of the holders of his chair to deliver.

The first of the proposed measures would imply an alteration in one of the ordinances for graduation in medicine (No. 8, clause vi. 4.) Such alteration can be made by the University Court only, with the consent, expressed in writing, of the Chancellor, and with the approval of Her Majesty in Council. But to alter in favour of female students rules laid down for the regulation of graduation in medicine would imply an assumption on the part of the Court that the University of Edinburgh has the power of granting degrees to women. It seems to the Court impossible for them to assume the existence of a power which is questioned in many quarters, and which is both affirmed and denied by eminent counsel. So long as these doubts remain, it would in the opinion of the Court, be premature to consider the expediency of taking steps to obtain, in favour of female students, an alteration of an ordinance which may be held not to apply to women.

Though the Court are unable to comply with any of the specific requests referred to, they are at the same time desirous to remove, so far as possible, any present obstacle in the way of a complete medical education being given to women, provided always that medical instruction to women be imparted in strictly separate classes.

The Court are of opinion that the question under reference has been complicated by the introduction of the subject of graduation, which is not essential to the completion of a medical or other education. The University of London, which has a special charter for the examination of women, does not confer degrees upon women, but only grants them "certificates of proficiency." If the applicants in the present case would be content to seek the examination of women by the University for certificates of proficiency in medicine, instead of for University degrees, the Court believe that arrangements for accomplishing this object would fall within the scope of the powers given to them by section 12 of the Universities (Scotland) Act. The Court would be willing to consider any such arrangements which might be submitted to them.

According to the return furnished by the medical officer of health, the cases of small-pox are decreasing. On the 7th the number of cases in hospital was 158, as compared with 163 on the corresponding day of the previous week. Since the opening of the hospital on the 5th of December, 288 cases have been admitted, of which 42 have resulted in death.

Sir Robert Christison, having entered on the fifteenth anniversary of his appointment as a professor in the University, the event is to be celebrated by a banquet on the 25th.

Foreign Medical Literature.

IDLENESS A CAUSE OF SUICIDE.

(Translated by JOSEPH COUTANCEAU.)

MAN has the mission of working for himself, his relations and others. His existence and his family's are only secured in comparison with it, and yet one could not imagine the prodigious number of individuals who feel an unconquerable reluctance for work. It has been said that if, instead of overwhelming children with laborious works which are not at all in harmony with their tastes, aptitudes, and inclinations, study may be rendered agreeable to them, their idleness would be subdued. The remark is just, but the immense majority will prefer play, dissipation and idleness to any study whatever, even if tasteful to them. The streets and public places are crowded with children, who contract from their very youth the habit of doing nothing and the abhorrence of superintendence. Go into the public or other offices, you will be struck with the carelessness and the ease with which many clerks perform their duties. Go through the manufactories, and you will soon be well aware of work being a burden, which most bear but impatiently. When history speaks of our period, there will be a page for the National Workshops? How many fellows have I known who spent their time at the *café*, talking, loitering, although waited for at business appointments! They had been informed that an excellent opportunity occurred, and that they must make haste; in spite of need, they were not in any hurry for it, and never arrived in time. It may be said, without any fear of being mistaken, that with anything short of an immense reformation, the world will not do otherwise than still belong for a long time to those who have an active aim towards which they resolutely and perseveringly proceed.

Fifty-six individuals, nearly the eighty-secondth part of the general number, have committed suicide on account of their impossibility of living without working, and of the disgust inspired in them by work. Some were fond of pleasure and of women, but would not do anything to give satisfaction to these propensities; others, without energy and courage, only got up very late to go to their office or place of business in spite of the reprimands, and even often in spite of the corrections. This one, lazy and greedy, coveted all he saw, spent his life in front of the shops, often bought without being able to pay; that one, without stability in his mind, but his unconquerable reluctance for any regular occupation, being by turns a traveller, a soldier, a deserter, a clerk, a servant, haunting the public houses, the girls and gambling, fell in the most frightful distress and ended by suicide.

Most of them manifested from their youth the utmost reluctance for all that required some work. They were thoughtless, giddy, and careless. There is especially a class of men among whom idleness seems innate; they are the servants. It might doubtless be wished that their masters would give them better examples, and would not forget that they are men and Christians like themselves; but it must be admitted that most of the servants assume that condition by weariness of regular work.

Mobility in the mind existed with many of those individuals, they continually proceeded from one scheme to another, and changed their places as their clothes. One of these wretched beings answered his parents who induced him to assume a profession, that he would rather die than be wearied by going and spending his days in a manufactory. It has been already remarked, that very few men like their condition; we admit that many have not been consulted on their choice, but we believe also that we are right in saying that it also depends on the fact, that a great many would not have any.

Literature.

NEUMANN'S SKIN DISEASES.

WE are glad to welcome the text book of the learned Vienna teacher in our English tongue. Dr. Pullar has, with the special permission of the author, translated into English, Neumann's text-book (a) which is in constant use in the Vienna school, and contains an accurate account of German research in Dermatology, and is especially full in the microscopic department. While dermatologists are so much divided it is scarcely to be expected that the opinions of Hebner and Neumann will find general acceptance, but we think it a good sign that a translation of a representative German work should be brought out, and we tender our thanks to Dr. Pullar for the great care with which he has executed his by no means easy task. Here and there we naturally expect to find some of the indications of the peculiarities of the original, but these are not so numerous or so unhappy as to interfere with the general result. In fact, the translation is a success. It is an important point that the translator has had the privilege of working with the proof sheets of the new edition, as this contains much new matter, especially that part in relation to parasitic diseases, and to some changes in the skin in old age. We have therefore a first-class text-book of German Dermatology brought down to the latest time by one of the most accomplished teachers of the great Vienna school.

(a) "Text-Book of Skin Diseases." By Dr. Isidor Neumann, Lecturer on Dermatology in the Imperial University of Vienna. Translated by Alfred Pullar, M.D. London, 1871. R. Hardwicke.

◆

PHRENOLOGY (*a*).

Here is a very elegantly got-up book about Phrenology. Its author is evidently a firm believer in the so-called Science of Phrenology, and therefore proportionally conscious to diffuse it. We doubt whether he will gain many disciples in the nineteenth century. The volume's chief attraction consists in a series of portraits, phrenologically designed, of eminent men, underneath which the author has placed in order their mental characteristics as considered from a phrenological point of view. It is manifest, however, that any newspaper reader of average ability could have constructed the analyses of character in question. The author has not given us much that is new. He commences with the fundamental principles of Phrenology, giving an outline of the labours of Gall, Spurzheim, Comte, and other enthusiasts. Regarding Phrenology from a retrospective point of view, it certainly does not seem to have repaid the time and labour bestowed upon it. Its disciples have changed their texts several times, and it is still unsettled which organs, or rather which bumps, are to be assigned to particular functions. The author goes on to treat of the brain as the organ of the mind, about the temperaments, and the relations of the brain and nerves. Having expounded the principles he applies them. We cannot afford space for a quotation from his book, and all we can say in addition is that on reading the book conscientiously there does not appear to be any more in phrenology than in physiognomy, palmistry, or any other exploded so-called sciences. Nevertheless, there are some persons weak-minded enough to believe in Phrenology, and to such people this volume may perhaps be welcome. It is certainly well got up, and the illustrations make it appropriate as a table volume.

◆

NEW EDITIONS.

Ringer's Therapeutics.

When a man has achieved success he is too often prone to rest on his laurels. For this reason the second edition of Ringer's Therapeutics (*b*) has somewhat disappointed us. The reviewer of the first edition in this journal spoke very favourably of it, and it was so well received by the Profession that we hoped to find in this a full account of the progress made in therapeutics during the interval that Professor Ringer has had. It is true that this interval has not been long, but much has transpired that ought to have been noticed. We opened the volume at the first page, and find it begins with Oxygen, but strange to say, the half page devoted to this agent tells us nothing of recent researches. But worse still, its statements are positively erroneous. We could scarcely believe our eyes when we read the first statement of this handbook, that is "Oxygen is at present rarely used in medicine, as no ready way of preparing or applying it has yet been devised."

For a professor of therapeutics in a large London medical school to give expression to such a mis-statement, was, to us, so amazing, that we naturally turned to a few other articles to see whether the revision had been more careful elsewhere. The article on nitrous oxide gas, which was good enough when the work first appeared, should have been re-written. Then there would have been no difficulty in describing the newest modes of administration. The articles on Digitalis and on Aconite, as well as many others, remain substantially what they were, although in the former particularly, we should have looked for further information.

Bismuth and its preparations are dismissed without amendment. We must confess too, that we are greatly disappointed, considering the very important investigations that have lately been made, with the article on Opium.

Nitrite of Amyl makes no appearance, but perhaps this part of the book was printed off before the author had noticed that this drug was coming into use. We are surprised, however, that Bichloride of Methylene is with other bodies, relegated to a foot-note quotation from Dr. Richardson's lecture on Anæsthetics. This reminds us that Dr. Ringer seldom condescends to give authority for anything—a fact we can only account for by his intending his work as a class-book. Still it looks as if no credit were to be given to very earnest workers in therapeutics, and we confess that we should have been glad to see a few names mentioned. Iodoform is fortunate enough to get half a page, and Chloral Hydrate obtains four pages. There is a good nosological table, an index of remedies, and an index of diseases. The work is well got up, and does credit to Mr. Lewis. With the drawbacks we have mentioned, it is a useful work, but we hope the next edition will be brought up to date.

◆

Correspondence.

THE ARTS OF SECRET POISONING.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—Nearly twelve months since, you gave publicity to a few observations on the art of secret poisoning, that then attracted some attention. Since then, a retired colonel in the army, long resident in India, has informed me of the use of a certain preparation, the effects of which are well known to many old residents in the East, as practised by the Thugge with such deadly certainty, that they could calculate the deaths of their intended victims, whether at the expiration of one, two, or three months, from the time the aroma (which he designated *tophayne*), was inhaled either through the ordinary mode of breathing or smelt through the nostrils, and that with such unerring and destructive effects, that when this poison had once entered into the system, escape with life was impossible, as there was no certain antidote known to the medical faculty in the East, capable of neutralising its malignant as well as deadly influence.

In immediate connection with this subject, the author of Waverley in the notes to Kenilworth under the Title Letter G, Dr. Julio, states that the Earl of Leicester's "*Italian Physician*, was affirmed by his contemporaries to be a skilful compounder of poisons, which he applied with such frequency, that the Jesuit Parson extols ironically the marvellous good luck of this great favourite in the opportune deaths of those who stood in the way of his wishes,' and then proceeds to give 'a curious passage' from that writer's, Leicester's "Commonwealth," p. 23.

As the paragraph there cited most graphically as fearfully illustrates the art of poisoning, as practised not only by The Mèdèci in Italy, but also in this country during the reign of Queen Elizabeth, and still more recently in our own dominions, with such fearful certainty and precision, I trust you will pardon its republication from vol. 2, p. 878 of the recent edition

---

(*a*) "Phrenology, and How to Use It in Analysing Character." By Nicholas Morgan. Illustrated by numerous portraits and other engravings. London: Longmans, Green, and Co.

(*b*) "A Handbook of Therapeutics." By Sydney Ringer, M.D. Second Edition. London: H. K. Lewis.

of Sir Walter Scott's works, by Messrs. Adam and Charles Black, 8vo. Edinburgh, 1867.

"Long after this he fell in love with the Ladye Sheffield, whom I signified before, and then also had he the same fortune to have her husband dye quickly, with an extreame rheume in his head (as it was given out), but as others say, of an artificiall catarre that stopped his breath."—Parson's Leicester's "Commonwealth," p. 33.

From a well founded suspicion that this very malignant and infernal art of *tophayne* is not confined to India alone, but has extended to other parts of the British Empire, nearer home, and also that the medical faculty may sometimes be led to attribute to ill ventilated water-closets, diseases that may very possibly ensue from other more malignant causes, of which they may not have the most remote suspicion, is the very best apology I have to offer for now recurring to this subject, subscribing myself Yours faithfully,

"VINDEX."

London, 1st January, 1872.

⁂ We insert this paragraph in deference to the very distinguished position of our correspondent; but we are not of opinion that we are in such danger as he seems to suppose.—ED.

◆

THE CIRCULATION OF THE BLOOD.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

DEAR SIR,—I beg to thank you for your kindness in publishing in your Journal of the 29th ult., my communication regarding the real authorship of the circulation of the blood. As in your issue of the above date there are, in the Greek quotations, some typographical errors I shall be much obliged by their being corrected in your next. The first Greek quotation should run thus: *καὶ πηγὴν τον περιφερομένον σφοδρῶς ἅιματος* and the second, *τὰ τῶν φλεβῶν ρεοι νάμοτα.* In the P. S. the word should be *φλεβῶν.*

I am, Dear Sir, yours much obliged,

JOHN J. MCKEOGH.

Thurles, 1st December, 1871.

◆

TWIN BIRTHS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Where, or in what part of my *first letter* (as quoted by Dr. Luther), that after the birth of the first child "the midwife called me aside," what I did say, was, 'having been taken aside (the child of course) by a nurse tender, &c. Now in some out of the way place, the terms nurse-tender and midwife may be considered as synonymous. We in the north, however, make a wide distinction, then follows the imaginary consultation, the phantoms of Dr. Luther's own brain.

It would be an utter absurdity, not to speak of a waste of time, which I have not at command, to reply to such a production. It is quite clear that my letter of the 20th has hit the mark, and brought out your correspondent in his true colours. No further words of mine could add to the condemnation his letter of the 27th inst. carries on its own front, and must produce the same condemnation in the minds of your readers in general, and obstetricians in particular. Of one thing I am certain, he will in future "evince" a less "predilection" to take up the pen of the critic? Would that as much could be said of the forceps.

I remain Sir, truly yours,

R. G. SHEIL, M.D.

Killyleagh, 28th December, 1871.

◆

THE INTROSPECTION OF WOMEN.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Your impartial conduct in inserting former communications on both sides of this subject and the persistent suppression of evidence emanating from scientific opponents of the Contagious Diseases Acts by the *Lancet* and *British Medical Journal*, have induced me to ask again for a small modicum of space in order to place before your readers the ground on which many of our best men and women, both in and out of the profession have consistently opposed the introduction into this country of any system analogous to that of the Contagious Diseases Act. It appears to me established beyond question, that the Contagious Diseases Acts violate the first principals of morality, namely, equal laws. That the effort to promote the salubrious practice of fornication, which all truly religious people regard as a deadly sin, is calculated to raise the most bitter opposition from all such persons, while the gross violation of the fundamental laws and sacred personal rights, hitherto guaranteed to every British subject,—the employment of spies, and the process of self-incrimination which they involve, must necessarily alarm all those who believe as I do, that, "The dearest interests of this country are its laws and its constitution, setting aside however, all these important considerations, it appears to me, Sir, that the authors, promoters, and would-be extenders of laws, like these are bound to show,—First, that there is an undeniable necessity for exceptional legislation; Second, that the means proposed are certain to attain the end in view; and lastly, that no less disgusting measures will suffice. I believe that on every one of these ground these laws utterly, undeniably, indefensibly break down. First, as to the necessity for exceptional legislation, it is a fact that of the men who voluntarily incur the risks of illicit intercourse in this country, a large proportion escape disease altogether. I know gentlemen who in spite of habitually repeated risks, repeated during several years, escaped disease altogether, and very many more who have suffered only from one or two slight attacks of gonorrhœa, which have not only failed to entail any ill consequences but have really, on the principle that a burnt child dreads the fire, effected much good by the fright and annoyance they have occasioned; moreover no man of experience will question the fact that the vast majority of those who inoculate themselves with venereal diseases, suffer only from affections of no great consequence either to themselves or others. Dr. Balfour in his evidence before the Commons' committee remarked that, even so far as soldiers are concerned and regarded as a financial question, it would not be worth while to legislate for either gonorrhœa or non-infecting sores—mere local accident, which did not infect the system, and yet it is a fact that 75 per cent. of all cases of venereal diseases are cases of gonorrhœa, and that of the remaining 25, nine out of ten are simple sores not followed by secondary symptoms and even of less consequence than gonorrhœa, while it is well known that of the remaining 8 per cent. of true syphilis, the vast majority are readily and permanently cured, never suffering again themselves or entailing disease on their offspring.

Fournier says only 5 per cent. of those cases of constitutional syphilis, if judiciously treated, suffer seriously, a point on which Lancereaux and other great authorities are agreed, and which most men who have had any experience in the treatment of such cases can confirm. In country towns and districts gentlemen who have practised for many years inform me that they hardly ever see a case of true syphilis, that inherited syphilis is rare, and that such cases as have come under their notice, many of whom from residing in the locality have remained under observation for many years, are permanently cured by ordinary remedies and have healthy offspring. Dr. Druitt, President of the Association of Medical Officers of Health for the Metropolis, has remarked that cases of syphilis in London are few and soon got over. Mr. Acton says death is never heard of, and that surgeons may practise in that special branch for many years in London, a centre to which all bad cases gravititate, without meeting with a single case of mutilation. Mr. Skey and Mr. Jonathan Hutchinson, both declare that the public entertain grossly exaggerated notions on this subject, ideas which have been studiously fostered by members of our own profession, while the latter whose authority on this special point is unquestioned, declares that inherited syphilis does not affect 1 in 5,000 of the innocent children we are so pathetically called upon to protect. Not long since twenty of the leading general practitioners in London, each with a visiting list of from thirty to forty families daily, met to discuss this question. "Do you see the effects of syphilis manifested in the cases which habitually come under your care?" Eighteen replied in the negative, and it is stated that the remaining two practised in the lowest districts. When the North York Militia were in training at Scarbro' last year an order came down from the War Office for the inspection of the men; this was carried out, and the surgeon assures me that there was not a single case of sore or syphilis, and only three cases of gonorrhœa in the regiment. A similar fact is recorded in the *Lancet* by the surgeon of a regiment of the line quartered in a manufacturing town where the Contagious Diseases Acts were not in force, who declared that there was not a single case of venereal disease among the men under his care. Dr. Balfour's tables show that at the very time when an outcry was raised by the Contagious Diseases Acts promoters, about the appalling prevalence of venereal disease, that this class of affection had actually been falling off among the troops so satisfactorily that had it occurred after instead of before the enactment of these measures, the authors would have pointed to the results as conclusive evidence of the efficacy of the system. It is needless to multiply such instances, they are in full accord with the experience of every man who has had any experience on the subject, indeed, it is a fact that scarlatina and numerous other diseases which occur in daily practice from which patients suffer through no fault of their own, and for the prevention of which there has never been any attempt at outrageous legislation, each can use more devastation in one year, than syphilis in twenty. I am well aware Sir J. Paget, Sir W. Jenner, and others, have described syphilis as a most serious malady, and I am not disposed to deny for one moment that it is in some instances a cause of relapsing illness to the original sufferer and a source of detriment to the offspring, but such cases are exceptional and rare, and as to the terrible cases which the unthinking public and many Parliamentary men have been led to suppose are fair types of all cases of venereal disease, they bear about the same relation to the mass of cases, gonorrhœa, soft sores, and mild syphilis, that fatal hydrophobia does to innocuous dog bite. So much for the necessity for state interference. Now let us see how far such measures either have diminished or are calculated to diminish the evils with which they profess to deal. One of the most interesting facts in connection with this branch of the subject is furnished by the tables of Messrs. Puche and Fournier, quoted in Lancereaux' last edition, translated by the Sydenham Society. These gentlemen anxious to trace syphilis to its source conducted a series of most elaborate enquiries, and whenever a patient suffering from this affection presented himself, they, wherever possible, ascertained the source of disease, and it was discovered that of 873 syphilitic patients, positively 625 contracted this worst form of venereal affection from public prostitutes, declared clean for safe usage by the examining surgeons. Dr. Macloughlin, who practised 27 years in Paris, adopted a similar plan and confronted wherever possible the patient and his infector, and arrived at similar conclusions, while Dr. Vintras, in his evidence before the venereal commission stated that, at least two-thirds of the cases of syphilis were derived from the registered prostitutes of Paris. It is plain, therefore, that the practice of inspecting women, does not guarantee freedom from disease. Many however say, well! it does no harm. This I believe to be a serious error, the fact that a woman has been examined and declared free from disease, is the greatest temptation a man can possibly have to incur the risk of infection, and moreover, no one acquainted with the history and pathology of syphilis can doubt that women who are introspected repeatedly one after another, many of whom although diseased appear free from disease, with the same instrument, are exposed to great risk from mediate contagion, as to detection of disease. Mr. Simon, and Dr. Aitken, the Editor of the *Medical Times and Gazette*, and every authority who has ever written on the subject, all concur in stating that, the poison of syphilis is so insidious and lurks where least expected that, it is almost impossible to keep it out, in fact the condition that communicates true syphilis in the female is in *so many* instances to be known *only by its effects*, that inspections not only fail but aggravate the evil. Thus, I believe, government fail in their object, by creating a false security, by spreading infection, and also by fostering a class of clandestine women who evade the police, and when diseased, decline all means of cure, from fear of being forced by police spies, into the ranks of notorious prostitutes. What is true of syphilis, is true also of the minor affections. It is impossible to say whether soft sores are of venereal origin or not, and the merest tyro in medicine ought to be aware of the fact that leucorrhœa, from which most women suffer, is perfectly indistinguishable from various stages of gonorrhœa. Mr. Jacob Bright, has shown that a number of women suffering from no form of venereal disease had been imprisoned in the Royal Albert Hospital. If I am told that the Acts have effected great good in our garrison towns in reforming women and diminishing disease, I reply that the Government tables show that 97 per cent. of the women treated in hospitals resume their former habits, and that the tables which are supposed to show the beneficial effects of these Acts among our soldiers, although made on a superficial view to show beneficial results, demonstrate on analysis that no good results have been attained. This fact I shall be happy to demonstrate to the satisfaction of your readers in a future letter, if you will accord me space.

I am, Sir,
Your Obedient Servant,
CHARLES BELL TAYLOR, M.D., F.R.C.S.

Medical News.

Royal College of Surgeons of England.—The quarterly meeting of the Council was held on Thursday last. Mr. Erichsen's motion, that vacancies in professorships or lectureships should be advertised, and candidates invited to apply for vacancies, was carried. Sir James Paget's motion —"That it is desirable, before proceeding to any nomination of members for election to the Fellowship, under the 5th clause of the Charter of 1852, that the Council should determine the conditions under which the election should take place"—was carried, but considerable discussion arose on a proposal to restrict the honour to men of science not in practice. Eventually it was determined to postpone the nomination of candidates for a twelve month, and refer the whole matter to a sub-committee for report. The President announced that, in consequence of the serious illness of Mr. Partridge, it would be necessary to fill up the vacancy in the Court of Examiners caused by Mr. Cock's retirement without delay. Sir J. Paget, Mr. Prescott Hewett, and Mr. Charles Hawkins announced their intention of not becoming candidates for the office, Mr. Simon gave notice of a motion requiring the Examinerships to be advertised in the same terms as the motion relating to the Professorships.

Glasgow Infirmary admitted during last year 6,014 patients, being 248 fewer than in 1870, owing to the subsidence of the relapsing fever epidemic. The daily average of patients in the hospital was 482, as against 513 in 1870. The total expenditure was £18,802 6s. 10d., the extraordinary revenue including a donation of £5,000 from Mr. John Freeland, of Nice.

Dr. Liebreich having been consulted in respect of an inflammation of the eye from which the French President has been suffering for some days, has declared that there is no cause for uneasiness.

Teetotalism in France.—The French anti-tobacco association is widening the field of its operations, and now includes alcoholic liquors among the abuses which it aims at remedying. This is the first temperance society established in France.

Dr. Frederick T. Hulke has been placed on the Commission of the Peace for Deal.—Mr. D. P. Maurice, F.R.C.S., was qualified as a County Magistrate for Wiltshire at the last Quarter Sessions held at Devizes.

The Prince of Wales :—The Last Bulletin :—The following official bulletin was issued on Sunday last: "Sandringham, Jan. 14:—His Royal Highness the Prince of Wales continues to make satisfactory progress, and is daily gaining health. Some time must yet elapse before the strength is fully established. No further bulletin will be issued."

WE understand that an important division has been taken within the last week in the College of Physicians as to the future admission of Fellows; the former law on the subject having been annulled by the decision of the judges in Dr. MacSwiney's case. If we are correctly informed, it was proposed that, for the future, the names of candidates for admission should be submitted to the College, who should elect two of their number, and that the sense of the College as to the admission of one or other of these two persons should be taken at three meetings of the College. This proposal was very vehemently opposed by Sir Dominic Corrigan, on the ground that, as a great majority of the Fellows are Conservatives, it would inevitably close the door against the admission of candidates of the political views which Sir Dominic Corrigan may be supposed to represent. After a succession of animated debates the vote was taken on the subject last week with the result of the rejection of the motion by a majority of one.

NOTICES TO CORRESPONDENTS.

CLINICAL NOTES AND OBSERVATIONS.

By Henry Lee,

Surgeon to St. George's Hospital.

II.—Secondary Mortification from Disease of the Arteries.

Changes of various kinds are found after death in the coats of arteries. These consist chiefly of steatomatous and atheromatous deposits, and of cartilaginous and bony thickening. When the curdy atheromatous deposit occurs between the internal and middle coats of an artery, or the pulpy changes take place in the internal coat, which has been denominated the steatomatous condition, the internal coat becomes separable with morbid facility from the middle, it is thickened, and presents often a dull opaque colour. As the disease advances, the altered internal membrane gives way, and the deposit, whatever its composition, is exposed to the current of the circulation. If the deposit has, as often happens, undergone fatty degeneration, it will be generally found softened to a greater or less extent, and to consist of oil globules, cholesterine, amorphous fragments, and earthy crystals.

The following cases, collected from different authors, illustrate some of the most interesting facts of this most important disease :—

G. L., æt. 62, was admitted into the hospital at Florence. She is a peasant from the Appennines, accustomed to live on bread, beans, chesnuts and weak wine. She only eats meat twice or three times in the year. About sixteen days ago she experienced severe burning pain in the whole of the left hand from the wrist to the ends of the fingers; the latter acquired a black colour in the course of four or five days, and the gangrene has ever since gradually extended; the pulse is very visible in both carotids, 120 in the minute; pulsation is distinct in the outer side of the right subclavian, not so in the left; the arteries of the right arm and forearm pulsate well, those on the left side cannot be felt; the left posterior tibial artery pulsates indistinctly, the right one does not do so at all. The same remark applies to the dorsal arteries of the feet, both lower limbs as far up as the knees are œdematous; the fingers of the left hand are semiflexed, cold, motionless, senseless, black, and somewhat shrivelled. This condition involves the whole hand as far as the wrist. The following temperatures are ascertained with the centigrade thermometer, care being taken that all the parts are similarly circumstanced as to covering :—

Ward...		18½	degrees.
Inside of cheeks		24	„
Both arm pits		24	„
Bend of elbow	left	21	„
	right	23	„
Palm of hand	left	20	„
	right	23	„
Dorsum of foot	left	22	„
	right	20	„

Strength gradually diminished, the gangrene extended a little up the forearm, but did not appear in any other part of the body. Death occurred at seven p.m. on the 7th of October. Treatment adopted was bark and opium, with tolerably good diet.

Examination forty hours after death.—The abdomen contains about two pints of turbid, greenish fluid, with flocculi of lymph floating in it; the viscera of this cavity are healthy; about one pint and a half of limpid serosity in the chest; lungs healthy; heart small and flaccid, orifices healthy, with the exception of some calcareous deposit at the insertion of the aortic semi-lunar valves; atheromatous degeneration manifest in the arch and descending portion of the aorta, especially around the orifices of the intercostal arteries; there is one patch of calcareous degeneration near the origin of the subclavian artery, and another above the origin of the cœliac axis; firmly adhering to the last one is the lower half of a blood clot measuring two inches and three-quarters in length, half-an-inch in breadth, and a little more than a line in thickness; the upper half of the clot is loose, of dark red colour and rather soft, but the lower half is adherent, of reddish yellow colour and firm; the right, common and external iliac arteries are almost completely obliterated by a blood clot, the upper half of which is of darker colour, more uniform shape and softer consistence than the lower half; the middle portion of the clot, including some of the dark red and soft, and some of the light red and consistent portions, is firmly adherent to the arterial coats, which appear healthy; a fine clot is continued into the right external iliac for rather more than an inch; the left subclavian artery is decidedly redder than are the other great vessels springing from the aortic arch. On careful examination, the redness is seen to be due to capillary injection (?); this is most marked along the concavity of the artery. This injection extends to five inches beyond the origin of the superior intercostal. As far as this point the colour of the arterial coats is deep red; beyond it they are of normal colour, but very much contracted. On comparing the brachial, radial, and ulnar arteries of the two sides, those on the left prove to be decidedly the smallest. On slitting open the left subclavian artery from its commencement onwards, an obliterating clot seven inches in length is exposed; at its proximate extremity the clot is of dark red colour, smooth on the surface, non-adherent, of moderate consistence; a little further on it is softer, especially near the surface. Towards its distal extremity it regains consistence, acquires a lighter colour, and is so firmly adherent to the artery, that on attempting to detach it, it breaks up. Just beyond the coagulum the artery contains a whitish, rather dry, grumous substance, which adheres to, but admits of being detached from, the artery. Under the microscope it is found to consist of imperfect granular and pus (a) corpuscles.

M. C., æt. 85, admitted into the female clinical ward at Florence, on the 10th of February, 1852. Her mental faculties being somewhat impaired, she is unable to give a detailed history of her disease, but is positive that the gangrenous foot has never been black, but has, on the contrary, preserved its native colour. On admission, the right foot was of *dirty white colour*, shrivelled up and hard, almost completely separated from the leg at the ankle joint by the effort of nature.

February 18th.—The foot was removed on the 10th by cutting through a piece of skin at the anterior part of the ankle, it being the only remaining bond of union with the leg. The stump, which then looked red, has now a grey aspect; the tips of all the toes of the left foot are black and horny; they may have been so several days, but no complaint having been made, attention has not been directed to the part. Since admission the old woman has gradually grown weak, and is to-day moribund. I made the post-mortem examination on the 20th of February, death having occurred on the 18th, an hour after taking the foregoing report. No rigor mortis, a good deal of tympanitis, considerable œdema of right thigh and leg, none of left lower limb or of upper ones. The aorta, slit throughout its whole extent, is found to be extensively atheromatous, the deposit being comparatively limited to the neighbourhood of the mouths of the vessels which branch from the trunk, the aortic coats having undergone the calcific degeneration at three different spots, each in the vicinity of the point where the left sub-clavian, cœliac axis, and inferior mesenteric are given off. Innominate and common carotids, with their branches on both sides, notably atheromatous, but only one small point of calcification on each side. On the right it is situated at the bifurcation of the innominate, and on the left at the bifurcation of the common carotid. Atheroma, but no calcification in subclavian, axillary and brachial arteries on both sides. In the last-named it diminishes with the increase of distance from the heart. Both radial and ulnar arteries perfectly healthy. Atheroma and calcification in both common iliacs. The former but not the latter degeneration exists in both external and in the left internal iliacs. Right internal iliac healthy. In dissecting the femoral vessels on the left side, nothing peculiar is seen externally. A good deal of atheromatous degeneration is discovered on laying open the left common femoral, and also a small calcareous patch an inch above the origin of the profunda, which, on being slit up, proves to be perfectly healthy. There is slight atheromatous degeneration in the upper inch and a half of the left superficial femoral, but none in the remainder of its extent. On laying open the left popliteal artery, numerous calcareous patches are discovered in different parts of it. The upper portion of the artery is obliterated by a red blood clot, but lower down by a firm white clot, which extends down into the upper two-thirds of the posterior tibial. The remainder of this vessel is pervious; the corresponding anterior tibial pervious and healthy; the peroneal and plantars not examined.

Right Lower-limb Arteries.—Unusual difficulty is experienced in dissecting the femoral vessels owing to adhesions between them and the adjacent tissues. There is a marked vascular net-work in the cellular coat covering the common and superficial femorals in their whole extent. Its meshes are not very close, but of bright red colour. On removing the cellular coat, the artery remains pale. This red net-work contrasts strongly with the external pallor of the left femoral. On slitting open the common femoral artery, no atheroma, but just above the origin of the profunda it presents a *rectangular calcareous patch*, measuring a quarter by half an inch. In the superficial femoral is a little atheroma just below the origin of the profunda, and a small patch of it on the posterior wall of the vessel just about its middle. Deep femoral artery healthy; right popliteal artery contains numerous calcareous patches in its coats; at about its middle, the whole circumference of the vessel is calcified. Corresponding to this spot the artery is partly *occluded* by *a firm adherent whitish clot.* In dissecting this artery, I have found it decidedly more adherent than usual to the surrounding tissues. On its exterior, which looks white, are more vasa vasorum than usual. Anterior tibial artery healthy; it is pervious except in its last inch, when it is occluded by *white adherent clots* (this is the side from which the foot separated). Peroneal artery healthy. Posterior tibial looks normal externally, but on cutting it open, it contains a whitish firm cord; on cutting this across, it proves to be hollow; on slitting it open longitudinally, its interior is found lined by the inner coat of the artery. On examining the exterior of the cord, atheroma (proved microscopically to consist of *fat* and cholesterine) is seen in it. This examination, carefully conducted, proved to me that the cord was due to longitudinal splitting up of the middle coat of the artery. Contraction of the inner part of the said coat, including the lining membrane, so as to form a cylinder, which appeared in the cavity of the artery, but what was at first taken to be the whole artery, proved to be nothing more than the outer coat, with a part of the middle coat lining it.

Venous System of the Right-lower Limb.—The common and internal iliac veins are perfectly healthy. On slitting up the external iliac vein, its coats are of normal colour and consistence; in its interior is a conically-shaped, non-adherent, but consistent clot, extending from half-an-inch below the origin of the internal iliac down into the femoral vein. On laying open the common and superficial femoral veins, which have a slate colour externally, with a fine net-work of very small vessels ramifying on them, I find their coats decidedly thickened throughout, but especially so the upper inch of the common femoral, where the tunics feel and cut almost like cartilage, and are very closely adherent to a firm reddish clot in the interior of the vein; this clot effectually closes the terminal orifice of the saphena. From the entrance of this vein downwards the superficial femoral vein contains a clot, which becomes irregularly smaller and less adherent as it descends; it ceases completely about its middle, whereas above the orifice of the saphena the clot is quite dry; below it, it is bathed by a fluid in colour and consistency very much like chocolate and milk. Below the part where the clot ends the vein is filled with a fluid of this kind. Opposite the termination of the said clot the femoral is joined by a venous branch, on tracing which into the triceps extensor, its first part is found to contain more of the chocolate-like fluid, but further on it contains a fluid like good pus. On sponging this away, the lining membrane remains rough, in consequence of white matter remaining adherent to it. On removing the fluid from the superficial femoral, its lining membrane presents a similar appearance. Both these veins are preternaturally red where the white pus-like matter does not adhere to their inner coat. The deep femoral vein at its upper part is occluded by an adherent clot, which becomes softer and acquires more the character of a healthy venous clot as it descends. The muscles of the thigh are healthy. The external and internal saphenous veins in the right leg are perfectly healthy; their orifices on the face of the stump are closed by adhesive matter. The popliteal vein is of a purplish colour, with very close vascular network on its exterior, and is quite round, and feels solid. On slitting it open, it is found completely occluded in its whole length by a firm adherent clot. The anterior and posterior tibial veins are healthy; one of the peroneal veins is healthy; the other is occluded by a tolerably firm and slightly adherent clot (*a*).

(a) "Surgica Researches., By J. S. Gamgee.

In the body of a female 70 years of age, of small stature, emaciated person, and with œdema of the lower extremities, Professor Tidemann found the end of the trunk of the abdominal aorta above its division into the common iliac arteries very firm and completely closed. The length of the closed portion amounted to two inches, immediately above the closure the trunk of the aorta was something corded, and so also at the origin of the two common iliac arteries, the solid mass which produced the closure was a dark red incompressible, leathery-like fibrinous clot, which was firmly attached to the inner coat of the artery, and extended into the beginning of the iliac arteries; the arterial walls showed concretions or ossifications and the same were observed in the walls of the iliac arteries; the inner coat was in various points lacerated, and the scaly concretions projected into the canal of the artery. Bony patches were also found in the abdominal and thoracic arteries, and in the trunk of the femoral arteries the fibrinous clot was so firm that it could not be cut by the knife, and it consisted of solid layers placed on each other. It closed not only the aorta and the common iliac arteries, but the lower lumbar and the middle sacral arteries; the upper lumbar arteries were enlarged. The circumference of the heart was considerable, the left ventricle was enlarged and its walls were thickened. No lesion of the valves was found, and no morbid changes in the other organs were observed. This female had been admitted into a poor-house several years' previously on account of the debility of age. She had often complained of violent palpitation, constriction of the chest, and sleeplessness; her latter years she had spent mostly in bed, and she died with symptoms of marasmus.

A soldier, æt. 43, of a Swiss regiment, in the service of the Netherlands, who had been ill with asthma, and who, after labouring under symptoms of great oppression in the chest, irregular pulse, abdominal pulsation and dropsy of the abdomen, and œdema of the feet, died. Besides serum in the chest and abdomen, the heart was enlarged and its trunks were larger than usual; the aorta was enlarged from its origin and the arch was dilated aneurismally; the first intercostal arteries were narrowed and contracted, and then unusually dilated; the innominate was dilated and gibbous, the left carotid and subclavian appeared enlarged, the right auricle and ventricle were enlarged, the left ventricle was enormously enlarged; its walls were thickened and the muscular bundles on the internal surface were strongly developed. The muscles attached to the mitral valves were threefold larger than usual, the semi-lunal valves of the aorta were most degenerated; all were large and broad, and occupied with lobulated growths and appendages. From the mitral valve which is opposite to the orifice of the left coronary artery, projected a membranous lobulated appendage, one inch long and three-fourths of an inch broad, terminated by a long small fringe. The other edge of this valve was thickened and gibbous. From the uneven surface of the second valve depended a long fringe-like appendage. The third valve, lying over the surface of the right coronary artery was thickened, and its edge beset with fringed lamellæ. All these growths and appendages hung free into the aorta and contracted its orifice; the inner surface of the aorta and all its branches as far as the aneurismal dilatation extended was irregular, and occupied by the *steatomatous* degeneration, the walls were thickened to more than double.

In a case described by Dr. Thompson, the brachial artery was at the elbow imbedded in a hardened mass composed of the surrounding cellular tissue, veins and nerves, all adhering firmly to each other, and to the artery. The artery was impervious before dividing into radial and ulnar branches, its calibre was also contracted, and its channel was filled by a cylindrical clot of firm lymph which extended about one quarter of an inch upwards from the point of division and adhered firmly to the inner surface of the artery. The orifice of a large branch was situate immediately above the termination of this clot of lymph, the radial artery was obliterated for nearly one inch and a quarter, its canal was much contracted and filled with lymph adhering firmly to its internal surface, and terminating in small conical processes about two lines long, which projected downwards into the tube of the artery. The obliteration extended only to the commencement of the ulnar artery; the coats of the arteries in the obliterated space were hard, thickened, of a whiter color than natural, and adhered inseparably to the surrounding parts. In the leg the muscles were dark in colour, very flaccid and lacerable, and in the course of the incision copious clots of blood were brought into view, considerable hardness and adhesion were observed where the femoral artery perforates the tendon of the triceps, and in the upper part of the ham, the course of the artery immediately after perforating the tendon was found an ovoid sac, which contained a hard solid substance resembling lymph, of the size and shape of a nutmeg, and with its surface covered with *thick greyish-coloured fluid like purulent matter*. This coagulum adhered firmly only to the upper extremity of the sac, immediately above the sac; the tube of the artery was obliterated to the extent of half an inch, its coats were much thickened and its parietes, were in contact and mutually adherent. From the obliterated portion, a large conical coagulum extended up the vessel for three inches, for more than an inch and a half below the sac, the coats of the artery were thickened, and its canal was filled with a firm coarse line of lymph adhering strongly to the external surface, and sending a conical process half an inch long downwards. The sac consisted of several layers, the inner apparently composed of the dilated external coats of the artery, and the other layers of the surrounding cellular substance. Beyond the obliteration the popliteal artery was pervious and empty for the space of about two inches, its coats appeared sound, except that there was opposite the origin of a large branch a small conical rent or fissure of the internal coats. Below this point the artery was again obliterated to the extent of one inch and a half by lymph effused within its cavity, and adhering, though not firmly, to its walls. The closed portion terminated in a thin sac of the capacity of a small bean, containing *purulent* matter, and similar to that found in the sac of the femoral artery; this sac was lacerable, and its internal surface ragged and whitish. To the middle of its parietes was attached the origin of

---

(*a*) "Surgical Remarks." By Mr. J. A. Gamgee.

the anterior tibial artery, the coats of which were so much thickened, that its canal was nearly obliterated; below the sac the posterior tibial artery was filled for nearly two inches with lymph adhering to the vessel, and terminating in a conical clot where the peroneal artery is given off. The peroneal artery was for a short space natural, but its coats became suddenly hard and thickened, and its canal almost closed; beyond this point its internal surface was of a dark purple colour, and the coats of the vessel had lost their elasticity. The femoral vein adhered to the femoral artery, opposite to the dilated part of the latter; the coats of the vein were here thickened, and its diameter diminished. Below this, its cavity was, in several parts, filled with clots of blood, the aorta and femoral artery above the closure were healthy.

A mariner, 24 years of age, tall, of strong constitution and sanguine temperament, had spent three days in a very cold snow-storm on board a vessel. Mostly engaged at the pumps, he was violently chilled, and was thereafter attacked with intense fever, attended with much heat, thirst, great headache, sense of constriction in the throat, and great anxiety. The skin was the seat of a sense of burning which passed into itching. On the 17th of January, the third day of his disease, he applied to Meli, who found the face flushed, the eyes suffused and the pulse hard and tense, and the patient complaining of a pain in the throat, dfficulty in swallowing, and rheumatic pains which were felt sometimes in the chest, sometimes in the abdomen; the patient lost some blood, and laxatives and antimonials were prescribed. Though on the 18th of January the patient was better, yet on the 19th all the febrile symptoms were more intense. The skin was in several places red, and in others presented effusions of blood, as after beating, the pulse was very rapid, vibrating and in the left arm dicrotous; the patient complained of great thirst, anxiety, throbbing headache, and strong pulsation over the whole body. The skin was painful especially in the region of the large venous trunk, and the slightest touch and pressure aggravated the pain. The blood drawn the previous day was covered with a thick buffy coat, the serum was very scanty, and the clot was firm and tough. As Meli considered the disease to be inflammation of the vessels, from the quick and violent beating of the arteries, and the redness and tenderness in the course of the veins he ordered another blood-letting, and the use of fox-glove. Next day, the 20th, the patient was rather better, but the night had been very restless, the symptoms also continued, and on the 21st the extravasations on the skin were more numerous and larger; pure blood was discharged from the throat, and blood and bloody mucous from the bowels. It is, however, unnecessary to pursue the minute details. The symptoms persevered notwithstanding the use of blood-letting, general and local, and fox-glove with laxatives till the 29th of January. In the night between the 29th and 30th the patient had a violent fit of shivering, he became very restless and anxious, and was convinced of the near approach of death. Meli who was sent for, found him with shrunk features and dark blue complexion, the pulse tremulous, intermitting, and scarcely perceptible; the abdomen tense and burning and the extremities cold, with violent and agonizing oppression; the patient soon after expired. The body was inspected anatomically with the greatest care on the 31st of January and the 1st of February, the surface was emphysematous, and in different parts of the cellular membrane reddish serum was effused and there were ecchymoses. The nostrils and the rectum contained much blood, all the superficial and deep-seated veins of the lower extremities were filled with blood, and their walls were hard, thickened, and red coloured internally. The arteries were in the same state, the trunk of the femoral vein and artery was highly inflamed, thickened, and solid, and their coats were covered with thick fine network of capillaries filled with blood. Their inner coat was lined with a layer of adherent plastic lymph, which in different points presented consistent purulent matter, the abdominal cavity was filled with much reddish serum, containing bloody clots, the peritoneum was much reddened and covered with numerous fine red vessels; in several parts of the intestines and mesentery there were ecchymosed spots. All the vessels of the abdomen, veins as well as arteries, were reddened and felt hard, as if they had been injected with the usual injection matter; and externally and internally contained plastic lymph. In several places they were closed and united by the effusion of lymph, and in few places did they contain blood. In the anterior wall of the aorta, two inches above its division into the iliac arteries, there was found an opening smaller than a lentile, but no laceration was seen in the trunk; the arterial walls were swelled and much thickened, the calibre of the vessel was diminished, and the inner coat was of a brown red colour. At the point where the cœliac artery arises from the aorta there was a circular cording of the vessel which extended to the division of the vessel into the gastric, hepatic, and splenic arteries; this consisted of effused plastic lymph which resembled a false membrane, and could be detached by the handle of the scalpel. The inferior vena cava was in like manner inflamed, much contracted in its calibre, and to its inner coat were attached patches of false membrane which were like valves. The part of the vena cava ascending behind the liver contained purulent matter, the arteries and veins of the mesentery were inflamed, red, and hard, and the vessels of the intestinal mucous membrane were much filled with blood. A similar condition of the blood-vessels of the stomach, the liver, the spleen, the pancreas, the kidneys, the urinary bladder, and the sexual organs were observed. Their inner membrane was covered with thick fine net-work of capillary vessels, the arteries and veins of the upper extremities were greatly inflamed, and quite in the same state as those of the lower; the pulmonary arteries and veins were also inflamed, especially the trunks, though less than the arteries and veins of the abdomen. In the intercostal, bronchial, and œsophageal arteries, the walls were firmer and thicker than usual, and their inner membrane was inflamed. The heart had partaken in the general morbid changes of the vascular system, its chambers were enlarged and its walls were hardened and firm, the trunks of the coronary arteries and thin small ramifications, as also the coronary veins were inflamed, and externally covered with lymph which had exuded from the cellular membrane. The walls of the auricles and ventricles, as also the trunks of the arteries and veins were covered with numerous capillary vessels. The inner surface of the left ventricle was lined with a coat of lymph, which stretched over the columnæ carnæ and partly hung far into the cavity of the ventricle, and the layer extended into the left auricle, and into the beginning of the aorta. The inner surface of the superior cava was lined with coagulable lymph, the inner surface of the throat was reddened, the velum was swelled, the uvula enlarged, and the whole were covered with numerous capillary vessels. Some clots of blood adhered to the mucous membrane, the vessels of the brain and its membranes also presented marks of inflammation.

◆

LECTURES ON THE TREATMENT OF CHRONIC SKIN DISEASES.

DELIVERED AT

SAINT VINCENT'S HOSPITAL,

By E. D. Mapother, M.D., Professor R.C.S.;

Late Examiner in Surgery, Queen's University.

Lecture III.

To-day we will begin by speaking of that dry scaly eruption of constitutional origin which is commonly called Psoriasis (ψωρὰ itch), although itching is not a usual or long-continued character. The term lepra, which really indicates the same disease, is still less appropriate. You must be very familiar with the cuticular scales of a whitish, sometimes pearly tint, lying heaped on a rough red cutis, which mark the affection. In an early stage the scales on several spots of the skin present the appearance of drops of mortar. These scales are most abundant and most easily removed by scratching or by the rubbing of the clothes during the first few months of the case, and if the disease is general a handful may be taken from the patient's bed in the morning. The derma is thickened slightly, and its capillaries are enlarged, so that some of the characters of a chronic inflammation are presented. The papillæ are likewise greatly enlarged. Several unnecessary names are applied to the forms of the disease accordingly as the shapes and extents of the patches vary. Dr. Anderson names one form rupoid, as the scales heap into cones, but this I have never seen.

The extensor aspects of the knee and elbow are the most usual sites where in many people the cuticle is rough and crusty naturally, and where the bones are near the surface. The thighs, bony prominences at the shoulder, neck, and face, are the next most frequented sites, and from the two last named it generally creeps to the scalp.

There is a most remarkable symmetry between the patches on each side of the body which marks the systemic nature of the disease. In corresponding parts the distribution of the blood must be more like than in other parts.

It occurs in very healthy subjects, hence the popular prejudice against having it cured. Neither fever nor any other systemic condition attends the eruption with sufficient constancy to be regarded as a symptom. When it is widely diffused, diarrhœa and bronchial catarrh are frequent. The evolution of carbonic acid from the lungs is also much increased.

The etiology of this common affection is still as obscure as in the days of Willan. Many believe that it is connected with dyspepsia, and that the diseases may alternate. Want of animal food has been assigned as a cause, but I am inclined to think the want of fresh unboiled vegetables as a more probable one. Either error of diet, if discovered, can be readily corrected. It is not in any degree contagious. Its frequency may be learned from the fact that it forms 831 out of Dr. Anderson's 11,000 cases of cutaneous disease, being one-third oftener in the private than in the public cases. This able author regards it as a disease showing debility, from having seen it often in women nursing.

The sexes are prone to it in nearly equal numbers. The only serious fact you have to bear in mind when asked for a prognosis is, that seven or eight out of ten cases will relapse. If habits of daily bathing be acquired, not half that proportion will suffer from subsequent attacks.

It may interest you to know what treatment was pursued in Dublin forty-five years ago. It is described as follows by two of our most famous physicians.

"Venesection was twice performed; she was put on low diet, and in the course of the first three weeks leeches were repeatedly applied to the most inflamed parts of the surface. During this time she took daily a pint of decoction of sarsaparilla, and about two drachms supertartrate of potash. When the violence of the cutaneous inflammation was subdued by these means, we had recourse to the use of sulphur internally, together with warm baths containing sulphuret of potash. . . .

"As yet we have met with no case of scaly disease which has resisted this simple method of cure, and have not therefore found it necessary to have recourse to the internal use of either arsenic or corrosive sublimate."

The most famous remedy is arsenic, and if given for about three months in gradually increasing doses, most cases yield. Veterinarians give this drug freely to horses, and it especially improves their coat, and some specialists assert that it will bring out hair on scalps long bald in the course of old age. Dr. C. H. Jones regards it as a powerful stimulant to the vaso-motor nerves, and if a full dose be taken, the cutaneous capillaries contract so much that even a Turkish bath will not bring out perspiration.

It has been stated that arsenic brings out herpes, but I have no evidence in favour of it, and some against it. To-day you saw at the Dispensary James Brien, a boy aged nine, whom I have known to suffer herpes for each of the last three years, and he has never taken arsenic. Its recurrence in this instance also contradicts the new theory that it attacks only once in life; and although it appeared always in the area of the distribution of the external cutaneous nerve of the lumbar plexus, I never could discover any source of irritation of the roots, which is said by many observers to be present.

Arsenic should be pushed to the production of its specific effects, just as we do with mercury, and anything short of this must be useless.

I have found the compounds of iodine, arsenic, and mercury (that which is commonly called Donovan's solution) more efficacious than pure arsenic, as given in Fowler's solution. The solution prepared by that most able pharmacist is the best possible form. It is praised highly by German authors, but has been left out of the last edition of our Pharmacopœia. Authors who regard arsenic as a panacea for most skin diseases do not like it, as the sole credit of cure is robbed from their favourite. It should be given in 20 drop doses thrice daily in a couple of ounces of water about an hour after each meal, as it is then less likely to disagree. Pain over the stomach, a pricking feel in the eyelids, or conjunctivitis, point to the constitutional action of the drug, and the need for stopping its administration for a few days. It certainly failed in the case of a gentleman last year, to whom I gave it for three months. I then ordered half a grain of the protiodide of mercury in pill thrice daily. He did not return for nearly three weeks, instead of one week as directed, and he was then slightly salivated. As the eruption, which was most widely diffused, was quickly throwing off the scales, and the true skin had a red but smooth surface, I continued the mercury and kept up salivation for a week. The diseased surface became free from scabs, but red and most tender, so that movements of the body were most painful; indeed he might be said to suffer from a general dermatitis. He gradually recovered, and the disease has not returned. The cases are much less liable to relapses if treated by mercurials than by any other drug.

Black pepper, copaiba, cantharides (used 100 years ago by Dr. Mead), and such matters, which irritate the alimentary and urinary mucous surfaces, and thus derive from the skin, have been much praised, but we have not tried them in this hospital. The free use of mustard as a condiment might act thus. Carbolic acid in grain doses thrice daily has been said to cure recent cases by lessening the local hyperemia. Powdered liquorice makes a good pill mass for it.

The alterative and curative value of sulphur has been much talked of, but beyond the fact that it permeates the system and stains the silver worn on the body, we know little of its action. There is no branch of our art which is less worked than the really scientific investigation of the action of medicines, because it does not "pay," the learned therapeutist being quickly outrun in profitable practice by the empirical practitioner.

As a means of checking salivation, sulphur given in a drachm dose, rubbed up with mucilage or two or three drachms of the sulphur electuary, I have found to have great power.

In cases of pyrosis with the vomiting of matter containing the sarcina ventriculi, the evolution of sulphurous acid by giving five to ten grains of the hyposulphite of lime or soda proves a most prompt and sure mode of killing this cryptogam. Sir W. Jenner has found the solution of sulphurous acid most potent in the cure of skin diseases due to vegetable growths. The sulphur waters at Lisdoonvarna, Harrogate, Moffat, and Bareges are undoubtedly useful in some forms of psoriasis, especially if the syphilitic or gouty poisons can be assigned as causative. Dr. Anderson praises most highly the baths of Leuk. There, a promiscuous crowd of every kind of ladies and gentlemen sit for four hours under water, clothed in woollen dresses, taking meanwhile breakfast, reading, playing a game of chess, or chatting with bystanders, who are freely admitted.

Iodide of potassium is also a remedy, which I generally use if I have the faintest suspicion of syphilis. I often add to the mixture two or three drachms of liquor potassæ, and with this chemical alone Dr. Bellingham cured many cases in this hospital twenty-five years ago. It would act as an antacid most clearly useful if there were gouty symptoms, and as a diuretic. The dryness and scaliness of the skin in diabetes results from the excited action of the mucous lining of the kidneys, so that the indication for exciting it in psoriasis is not evident. The salts of potash with citric, acetic, or tartaric acids, are converted into the carbonate in the blood, and in the nascent state they are very active. The alkaline treatment, so far as I can find, was original with my distinguished predecessor.

Both hospital and private patients with psoriasis, and indeed most other chronic skin diseases, should take free outdoor exercise. The lungs, liver, and digestive organs are then stimulated by muscular work in what some would call a sun and air bath.

Warm or tepid baths of soft water, with free use of soft soap, that admirable agent we have spoken of so often, constitute the best part of the local treatment. The scales are softened, the infiltration of the derma is lessened, and the healthy skin is made to do double duty. Many writers speak highly of wet-packing as the hydropaths use it, and of covering the parts with india-rubber clothing, but I have no experience of either. In the intervals of the baths the body should be smeared with carbolic acid ointment.

When there were very thick layers of cuticle to be removed, I have preferred the simple vapour bath, which we use here by placing a spirit lamp (having a vessel of water) under a cane-bottomed chair, on which the patient sits, surrounded well by blankets.

The tars from various woods (especially oleum cadini from juniper) are largely used on the continent, and high fever, with dark-coloured fæces and urine, have arisen from its excessive application.

Hear Professor Wilson's remedy for psoriasis, or as he appears to consider it, squamous eczema. "Daniel Turner, the first of English dermapathologists (1710), left behind him a reputation for his—cerate, and we hope to be able to leave behind an equal reputation for the benzoated ointment of oxide of zinc, at last and apparently with some reluctance provided with a place in the British Pharmacopœia, upon whose pages it sheds unwonted lustre!" The compound described in this and many other grandiloquent sentences is made with oxide of zinc and lard, to which benzoin has been added to prevent rancidity. The eccentricities of this author are capped by the concluding pages of his recent "Lectures on Eczema."

Mercurial ointments, the blue, the white, the red, and the citrine, have all been vaunted, but if they do any good it is by their lard, for their mercury is not absorbed.

The only fact which has shaken my belief of the constitutional nature of psoriasis and the need for external treatment is, that I have seen Dr. Neligan suppress many cases where the eruption was very limited, by painting it over with fluid blister. The fluid of that kind in the Pharmacopœia is the safest. We often use Burt's Vesicating Fluid, but having lately caused severe inflammation on the skin of a private patient of mine, I will discontinue its use.

The skin is the favourite seat of the first manifestation of constitutional syphilis, as it is the most superficial of tissues and the effects of the disease gradually appear in the deeper. That poison does not give rise to any eruption wholly peculiar—that is to say, any of the rashes we have been considering, and many others may be or may not be syphilitic. Antecedent or concomitant symptoms, and some slight points of colour and form, however, usually enable us to make the diagnosis, a matter of vital importance. The great chronicity, tendency to relapse, the dull coppery hue, rounded form, proneness to appear on the face, and absence of itching, may be taken as generally diagnostic. The concurrence of periosteal pains, sore throat, or iritis, make the nature of the case quite certain. Tenderness on and under the sternum is often present, and has been said to be pathognomonic. The general surface of the skin lessens insensitiveness in some cases. The polymorphism or variety of forms also characterise the syphilitic rashes.

You all know the doctrine so long accepted on the authority of our illustrious Carmichael—viz., that there were four varieties of syphilis, each peculiar in its primary characters and secondary eruptions. They were the papular, the pustular, the phagadænic, and the scaly, respectively preceded by a soft fungous sore, "the ulcer with elevated edges," the sloughing and ulcerating sore, and the hard chancre.

This theory is not correct, but its practical deductions to separate the cases fit and unfit for mercury, have rendered Carmichael one of the greatest human benefactors. Diday protects him from envious critics as "Ce profond observateur si méconnu si travesti."

Bassereau says: "I have seen only six patients affected with syphilitic rupia; five of these have had as a primary lesion phagadænic chancre, which might have foretold even then the form and the severity of the possible consecutive symptoms."

The most common rash appearing in perhaps over half the cases, and the mildest, is the erythema, or rose rash. Its red patches are not raised, disappear on pressure, and result eventually in a brownish stain. It follows in about six weeks the primary sore, sooner in warm weather, is ushered in by pyrexia, the temperature rising a couple of degrees for a day or two, and then comes out chiefly on the face and warm parts of the body, chest, loins, and abdomen. When the skin is exposed while examining the patient on a cold day, the patches keep their red tint, while the rest of the skin becomes paler. The mucous surfaces which we can see with the unaided eye or the laryngoscope, especially the back of the mouth, show increased vascularity as well as the skin. This circumstance has caused the case to be mistaken for scarlatina. It is less like measles, for the conjunctival and bronchial surfaces are seldom or never engaged, and from copaiba rash it is known by the latter being limited to the wrists, knees, and other joints. Children who inherit syphilis usually develop when about a month old an erythema about the nates, accompanied with condylomata about the arms. The emaciation and croaking senile cry are most characteristic. Jaundice often accompanies roseola.

Next comes perhaps once in four cases the papular eruption which, although noticed for the first time by Carmichael, is even more generally distributed than the rose rash. It often follows six weeks after the rose rash, but in some few cases it is the first eruption. The glands at the back of the neck are always enlarged, and there are usually low spirits, malaise, and pains like those of rheumatism in the fibrous tissues and bones, the patients feeling, as Ambrose Paré remarked, as if they had been beaten all over with sticks. The papules are larger and darker in colour than those of lichen. From proneness to suppurate and scale at the top they are more like those of acne; but we have seen how much localised to the face and neck that disease is, and how usually combined it is with seborrhœa and comedones. The papules brought out by taking iodide of potassium are not unlike those of syphilis. I am at present attending, with Dr. Jacob, a lady for otorrhœa, and two grain doses of the iodide have brought out a free papular rash on the face accompanied by the special catarrh.

The pustular eruption, sometimes described as a distinct form, is most usually a stage of the papules very quickly developed. Even with rose rash on the body there will be very often pustules on the hairy scalp, for reasons which I have mentioned when describing eczema.

We very often see here a pustular disease, ecthyma, on the legs of weakly ill-fed men about forty years of age, but the history of syphilis is often not proven in the cases. There are from three to twelve pustules on the front of each leg, each separate and about half an inch in diameter. The scab is brownish, sanio-purulent and irregular on the surface; when poulticed off, the scab leaves a superficial ulcer behind. This disease and rupia occurring from syphilis are often called tertiary symptoms, but the limits of secondaries are by no means clearly defined. The production of gummy tumours occur at the tertiary and quarternary periods, and gradually in the deeper parts the poison being centripetal.

Scaly venereal eruptions appear either as the first after the infection or more frequently as a sequela of the rose rash or papules. They are however rare in either way, and some described them only as a stage of the papular rash. The scales are much less copious than in ordinary psoriasis, the patches are more rounded, the edge being higher than the centre, and the usual coppery red tint is present. The extensor aspects of the limbs are not the exclusive seats of the disease. Baldness is a more frequently concomitant of this than of any other eruption.

For the two last years we have had no case of true rupia here, so that none of you may have seen it. It is so characteristic an eruption that if you ever meet it you will recognise it if the following points are present—A conical scab from half an inch to an inch in diameter at the base, with fluted marks round it like those on a limpet shell. If you twist this scab round a few times it will come away, leaving a conical ulcer as deep in the skin as the scab was in height. Successive scabs form quickly, even in a night, and rising up, give the conical shape. Depressed round scars about the size of a sixpence result, and they have been sometimes pointed to by boastful warriors as bullet wounds. They have been gained in conflicts other than martial, and as Sir D. Corrigan used to tell in his lectures, they are mostly on the posterior aspect of the body, and therefore evidence a timely retreat more than a dauntless advance.

The treatment of syphilitic eruptions is more fully agreed upon than that of any other class of skin diseases we have talked about. There are, I conceive, few, if any, who would not mercurialise a patient with any syphilitic rash if the drug had not been fully given before, and if the patient were not cachectic in the greatest degree. Diday indeed says "With roseola—wait, with a vesicular squamous or pustular syphilide—give mercury, with a papular syphilide wait, but watch." Age has really more to do with it, a man of 25 will often throw off any poison syphilis or typhus for example, without treatment; a man of twice that age will be crushed by them unless most skilfully treated. The extreme on the mercurial side must be set down as Ricord, who declares six months of mercurial treatment, *plus* three months of treatment with preparation of iodine, is the method which affords most permanent cures, and succeeds in a vast majority of cases in really neutralising the poisonous influence, that is curing the syphilis or most of its manifestations.

Salivation is best produced by the protiodide of mercury, first used by Biett. It should be given in doses of ¼ or ⅓ of a grain thrice daily.

I never could understand the advantage in such cases of inunction, baths with solutions of or fumigation with vapours of mercury. Infants indeed are best treated by the ointment spread on a flannel swathe. On the treatment of syphilis by mercury I would, however, advise you to learn Colles's book, sound and most practical as it is. Let me say parenthetically, that he was *the* surgeon of Dublin worthy of State honours, and that as he has a most worthy son and successor it is not too late to compliment our College of Surgeons in the person of its ablest councillor.

Donovan's solution in 20-drop doses is most serviceable in the more obstinate of the syphilides, as is also a compound of biniodide of mercury with iodide of potassium. However, we have the great authority, Hunter, teaching us that all mercurial preparations act in like manner, for they are all changed in the system into one compound, which I have striven to prove, is the bichloride (MEDICAL PRESS AND CIRCULAR, April, 1870). As there stated, I believe the copper and lead salts would act equally well with mercury in coagulating the low form of fibrin which abounds in the blood of syphilitic patients. Purgatives, or other eliminants, would be required to remove the effete matter.

In weakly patients with ecthyma or rupia, and already drenched with mercury, good diet, and wine or beer, are the best medicines, but bark preparations, with nitric acid or iodide of potassium, give aid. The value of the salt was first proved by Wallace, of our College, where so many proofs of his ability are preserved.

The sulphur waters, Lisdoonvarna in our country, Harrogate in England, Moffat in Scotland, and Barèges and Aix on the Continent, often work wonders in removing old scaly venereal rashes, as well as other evils from that fearful taint.

Syphilitic diseases of the nails are not infrequently seen, but we have not time to discuss them now.

Although ingrowing toe-nail is not a specific disease, I cannot forbear from reminding you of the treatment you have seen in this hospital very effectual. The patient's sensibility being dulled by a 30-grain dose of chloral, or by a few whiffs of chloroform, shove a strong scissors under the nail quite beyond the fold of cuticle which covers it; then clip the nail in two for its whole extent. Next insert a strong forcep under each half, or under the half to which the disease is limited, and roll it from the centre outwards. This mode I have never known fail, which I cannot say of two cases treated by excision of the matrix and nail, which I performed with the aid of two senior consultants.

Hæmorrhage from the vessels of the cutis occurs as a symptom of typhus, of small-pox (unhappily too often in our present epidemic), and of scurvy, but the only form which is treated of as a separate skin affection is named purpura. Willan placed it along with the contagious rashes or exanthems, and there it is retained to this day in the work of one specialist, who treats it with arsenic, purgative doses of calomel or emetic doses of antimony.

In all a vitiated state of the blood is the primary change, and I believe that in no case do the blood cells escape without rupture of the capillaries. It is the dissolved hematin which oozes through their walls and stains the true skin without raising the cuticle. A septic fitness of the blood is indicated by the fearful rapidity of putrefaction of the body after death. The white of the eye and the skin often show a jaundice hue. When the blood spots are small, in size varying from that of a pin's head to a pea, they are named petechiæ, from their likeness to flea bites, but the central wound distinguishes that mark. Those in the form of streaks are vibices, and larger effusions, like the masses of blood extravasated by blows, are called ecchymoses. Blebs of true clotting blood are only formed by direct violence very deeply bruising the skin and soft parts below it.

The dark blue, red, and yellow tints so well known to successively appear in the blood of a bruise, are also seen in the various states of purpura spots, which never coalesce.

In the uncomplicated form of purpura the mucous surfaces pour out blood, especially that of the nose, bowels, and kidneys.

Owing to gravitation the spots are most frequently in the lower half of the body, and in old people in whom the capillaries are weak, there is a further reason for the exudation of blood. In some old people the least blow will cause a great ecchymosis.

Chemists have not made out any special alteration in the blood. The same erroneous diet which will cause scurvy, I feel sure may cause purpura, which is so closely allied. It is said to occur in families marked by hæmorrhagic diathesis, owing to deficiency of fibrin in the blood.

I have never seen purpura accompanied by rheumatic pains, which is often described by continental writers, but I have often heard purpura patients complain of muscular and nervous aches, and Romberg calls "pain the prayer for healthy blood." Inaction of the vaso-motor nerves no doubt causes the stagnation of the blood which precedes its effusion. The occurrence of purpuric spots in cases of terrible disease, cerebro-spinal meningitis, render this highly probable, as I endeavoured to show in an account of the the Dublin epidemic of 1867, which I drew up for the Epidemiological Society. Pressure often brings out fresh spots in purpura, but did not in the above-named nervous lesion. Herpetic spots frequently appeared during the convalescence of those who escaped death, giving evidence of peripheral effects from central disease.

Among medicines used in purpura I should mention ergot of rye in 5 to 10 grain doses, and it acts by contracting the muscular coats of the vessels, and the muriated tincture of iron which is astringent, and then blood restorative.

If, as I have stated, the nervous system is the real seat of lesion, phosphorus, strychnia or other neurotonics seem worth trial.

Turpentine seems of use by astringing the capillaries as well as stimulating the heart and the muscular coat of the intestines.

I have often seen Dr. Neligan give an ounce of it or even a wineglassful when the bleeding from the alimentary surface was severe.

It frequently intoxicated the patients as much as a couple of glasses of whiskey would do. From such large doses I never saw strangury arise.

I will not detain you with any account of the anatomy and functions of the skin, for I hope you have learned all about them in your physiological course. Its extraordinary vascularity, secretion of three pounds daily and breathing power in aid of the lungs will occur to you in support of the assertion that the neglect of its functions must lead to serious diseases of internal organs. No hygienic habit is equal in value to the daily sponge bath, which I am glad to say is coming into increased use among the richer classes. Crowded together in a single tenement room, without complete separation of the sexes, our poor find complete ablution impossible, and although we have the softest and most copious of waters we are the most unwashed of citizens. The only cheap baths for the poor we had were those connected with the Mendicity Institution, Usher's Island. In 1866, the number of baths given was 18,000, of which forty-eight were gratuitous. They have just opened them at reduced prices, and they are admirably conducted; but in such a city as Dublin we should have a dozen public baths, not one. The closure of those in Abbey street and Westland row would indicate that the taste for clean skins is decreasing, for no good substitutes have been opened.

In 1866 over a million of baths were given, and 400,000 women washed clothes in the baths established in London under the Baths Act (9 and 10, Vic. cap. 74). The corporation of every town is empowered to erect such baths.

In the Ragged Schools of that city it has been found that great cleanliness, sweetness of the air, and freedom from contagious skin diseases have resulted from obliging each child to take a bath as they enter school.

Well-made yellow soap containing soda is hurtful in very few skin diseases, and for all is a necessity for cleansing the healthy skin. The alkali is required for the softening of the cuticle and removal of the sebaceous fat. Substitutes such as wash powder, do harm, and as Professor Wilson says, "they cannot follow the innumerable apertures of the skin, nor enter the mouths of the pores otherwise than to obstruct them. A skin cleaned in this manner may always be detected by a certain kind of shining, not to say greasy polish, and the whole complexion looks mellowed into a kind of *tone*, as we say of pictures in which dirt and time have softened and chastened the tints."

Very few words will inculcate what is desirable in the way of dress for skin patients. If the disease be chronic and indolent, such as psoriasis, let flannel be always worn, if it be irritable or inflammatory such as eczema, the softest and longest worn cotton will suit best.

◆

ON THE SENSE OF HEARING. (a)

By John P. Pennefather,

Surgeon to the Royal Dispensary for Diseases of the Ear.

Perhaps there is no subject or structure in connection with the human organism that has been more closely investigated by the few and neglected by the many than the subject of sound and the structures by which it is conceived. By experiments with the air-pump, first publicly demonstrated more than a century and a half ago, it was proved that a vacuum surrounding a body rendered that body incapable of originating sonorous vibrations, and thus an important fact in the theory of acoustics was established. That sound is conveyed by atmospheric undulations communicated by the vibrations of a sonorous body, and that these undulations reach the nerve of audition is no doubt generally known, but with this most shadowy idea of the realisation of a sense, and the composition of a structure so simple, yet so efficiently perfect and beautiful in its minutest details, it is too much the habit to rest content.

Sound is produced primarily by the vibrations of a sonorous body, but two circumstances govern the power and extent to which these vibrations may be transmitted, namely, the composition of the body as to its vibratory faculty, as well as the atmospheric condition by which it is surrounded. Thus incohating vibrations of equal power and from equal bodies as well as from equal gradations of distance, but initiating on an immediate surrounding atmosphere of unequal elasticity, strike on the ear with differing force, the vibrations from one quarter may be distinctly audible, while those from the other are scarcely perceivable.

Sound is conveyed by undulating aerial waves, and the manner by which the atomic atmospheric particles convey the sonorous pulses, has been illustrated by placing a number of glass balls in contact, by applying force to the last of the row at one end, it is transmitted from one to the other, until, reaching the last ball at the other end, it shoots it away. A far better illustration of the mode by which the sonorous pulses are propelled is to be gathered in the displacement of water by dropping a substance into it; we here see the circular undulations gradually expanding until the original force imparted is expended, at the outset the centre of the wave will be always observed to have the greatest volume. So in the vibrations of sound the undulations though spread out are most powerful in a direct line from the centre of their origin. Again, if we observe the sea beating against a cliff in which there is an inlet, the increased power with which the water rushes into the opening will be obvious; this may be accounted for in this way, the wave rebounding from each side of the entrance is met by the advancing undulation, and the body of water at each side is thus rendered more dense than that which is flowing into the cavern, to which it acts as a boundary. Thus in the undulations of sound as they strike on the surface of the side of the cranium the pulses are forced with augmented power into the meatus auditorus externus which is necessary for that actual physical impression by which alone the auditory nerve is stimulated to action. A curious circumstance is detailed by Professor Tyndall which proves that the undulatory waves embrace any object within the sphere of their action on coming into contact with it. The explosion which occurred at Erith in 1864 broke all the windows of the town though miles distant, fracturing those that were in a contrary directon as well as those which were facing it. In Erith Church, where the window sashes are constructed of lead, being partly flexible they escaped, but every window in the building was forced inwards without breaking a single pane of glass. Yielding at first to the shock the windows received the support of the air contained in the church and were thus saved from damage. This will show us the value of the air contained in the cavity of the tympanum in supporting its membrane from undue external pressure. For the mere perception of sound, without variation of tone, the vestibule is the only part of the organ essential. In zoophytes and in animals of still lower creation where even the rudimentary structure of a hearing organ is entirely absent, there is no perception of sound, and among the insect tribe comparative anatomists have pronounced it absent, but that insects are influenced by aerial undulations eminent zoologists allow, and attribute the faculty to the exquisite sensibility with which the antennæ of insects are endowed, the sonorous pulses agitating these appendages communicate the sensation. In the Molluscæ the auditory organs consist of small membranous vesicles. In the next order Crustacæ, the lowest of the Articulata, we find the vestibule covered at the base of their antennæ by a membrane analogous to the fenestral membrane of a higher creation, the vestibule contains a fluid in which are expanded the terminal extremities of the auditory nerve. In fishes there is a vestibule and three semicircular canals, but the entire organ is contained within the walls of the cranium ; it must be remembered that fish live in a fluid which is a powerful sound conductor. Anglers are well aware how necessary it is to cast their fly or bait gently in the water.

(a) Read before the Medical Society of London.

In Reptilia we find a rudimentary cochlea and imperfectly formed tympanum, which is described by Edwards as a dependence from the pharynx. In the class Reptilia we arrive at a formation which though imperfect is capable of perceiving different degrees of sound in rhythmical order. Of this power the snake charmers of India take advantage and by means of harmonic vibrations succeed in charming the most venomous of the class. In birds we arrive at another step in the formation of a perfect auditory structure in the addition of an external auditory canal. The tympanum of birds communicates with the diploe of the cranial bones which are filled with air instead of medulla. It contains also a single bone which adheres to the vestibular membrane and may be considered as the rudimentary ossicula of the mammalian order.

In Mammalia we find the organ of hearing complete, consisting of an auricle, external meatus, perfect tympanum, and perfect internal ear, The only difference observable in the class is that man from his higher sensorial development has a more perfect realisation of the sense, and that the organic structure is somewhat modified to suit the different requirements of the animals composing the order. Thus in aquatic mammals the auricle is necessarily small, and among the Carnivora it is smaller than among the Herbifera. That the auricle is of much value among quadrupeds for the acute action of the sense of hearing there can be little doubt ; who can have seen any of the equine tribe at some sudden noise casting the auricle backwards and forwards and turning its concavity in the direction from whence the sound proceeds but must allow that be it sense or be it instinct, the animal is aware that nature has provided him with the means of concentrating to a greater degree the sonorous undulations on the auditory nerve by the formation of the auricle. In man, though many authors have sought to disprove it, I entertain no doubt that the auricle unquestionably, in a much minor degree than among quadruped mammalia, is essential to the full and exquisite development of the sense of hearing. We thus trace the auditory mechanism, where lies the sense of hearing, through the different orders of creation, finding each part added according to the requirements of the animal. The ariel undulations having reached the auricle of a healthy organ are collected in its sinuosities, the channels of which will be all observed to lead into the cavity called the cochlea, where they are concentrated and discharged through the external auditory canal on to the membrane of the tympanum, which vibrates in ratio to the force communicated to it. This membrane which is composed of fibres radiating from its centre to its circumference, is peculiarly adapted for its office which is to intensify and communicate the pulses of sound which it has received to the ossicula auditus by means of the close attachment which it has to the malleus, one of this chain which consists of four bones, so articulated that their vibration becomes a multiple of that received from the membrane. They in their turn act on the membrane of the fenestra ovalis by the stapes which is in intimate relation with it. I contend that it is by this agency and by this alone that the sonorous undulations are conveyed to the internal ear. Writers on this subject, even of recent date, state that the bony parietes and the air contained in the tympanum are also mediums of transmission. Were the bony parietes capable of transmitting the pulses of sound to the nerve of audition, the external and middle ear were superfluous appendages, as the surface of the cranium would afford ample means of conduction. Unless the sonorous body be in actual contact with the bones of the skull, and its vibrations are thus imparted to them, the bony parietes have no other action in the sense than that of affording lodgment and protection to the mechanism by which the auditory nerve is aroused into activity. Nor can the small amount of air in the drum, a chamber which in its normal condition during life is scarcely capable of containing a pea be supposed to perform any other act than that of supporting the membrana tympani from undue external pressure, for not only does the air contained in this cavity speedily lose its elasticity, but inasmuch as the membrane of the fenestra ovalis is covered and the entrance to the internal ear blocked by the base of the stapes, its only means of action would be by lateral force on the ossicular chain, its quantity would however negative the idea of its possessing such a power. Some authors have suggested that the cavity of the tympanum is a reverberating chamber, and that in this way the impulses of sound are transmitted, but this idea is entirely untenable, for probably no formation could be worse constructed for such a purpose than the irregular chamber of the tympanum with its numerous spines and processes. That the waves of sound are capable of being focussed in a particular direction, is a well-known fact which we see every day applied, but the structure of the tympanum forbids such an hypothesis in connection with it.

We now come to the internal ear or labyrinth, the true seat of the organ of hearing, it is divided into three parts ; but to enter into a minute and particular description of this wondrously beautiful and complex structure would infringe too much on the time of the society. Hitherto, elastic air has been the physical power by which the vibrations have been so far conducted ; but, having arrived at the internal ear, they require, in such a confined space, a more powerful medium of conduction, consequently, we find the internal ear filled with fluid. In the windings of the labyrinth, are sacculi and tubes containing aqueous matter, in which are expanded the terminal extremities of the auditory nerve, and these sacculi and tubes are themselves surrounded by fluid. Thus, when the membrane of the fenestra ovalis is set in motion by the vibration of the chain of ossicles, the impulse is communicated to the fluids in which the terminal extremities of the nerve are expanded, and by the irritation of these nervous bulbous expansions, the sense of hearing is brought into action ; but, without the semi-circular canals and cochlea, it would be merely the perception without the distinction of sound, and further, were the vibrations of the ossicles imparted to the dense fluid confined within the unyielding walls of the labyrinth, unless some means of expansion were provided. Not only would the violent undulations be transmitted to the nerve with the same force they were received from the chain of bones, but all sonorous undulations would be without any distinguishing character. But the simplicity of Nature's provision for this is as in all her works, but in keeping with its efficiency. If we call to mind that a glass tube of even a mile in length, filled with water, cannot lose one drop without the whole column being agitated, the nature of this provision will be the more readily comprehended. As the impulse is received at the fenestra ovalis, it is transmitted from body to body in one unbroken wave throughout the windings of the internal ear, until it arrives at the opening of the foramen rotundum from a scale of the cochlea, into the chamber of the tympanum. This opening is guarded by an elastic membrane, which admits of the fluid contained in the labyrinth, expanding in proportion to the violence of the agitation communicated to it, and thus the nerve is protected from the effects of undue vibrations. We here recognise again the important part the air contained in the tympanum plays in supporting this elastic membrane from over-expansion and rupture. It is in the advance of this aqueous wave, if I may so use the term, that the gradation of sound are perceived, and how contained within the cochlea, is a perfect musical instrument discovered by Corti, and consisting, according to Kölliker, of three thousand strings or fibres, through the kindness of Dr. Pritchard, who has placed these very beautiful microscopical preparations at my disposal, I am enabled to show you a section of the cochlea, two sections of the bamuna spirales with rods, and a section of the canal with the membrane of Reisiner. By first looking at these plates, lent by Dr. Rutherford, of King's College, you may perhaps more easily understand the preparations under the microscope, which are most admirably prepared, and reflect great credit on Dr. Urban Pritchard. The nervous fasiculæ are further irritated to action by minute sharp pointed bristles, discovered by Max Schultze, and again we have minute bodies called Otolithes laying among the nervous filaments, these bristles of Schultze's, and cretaceous particles are probably provided for the reception of those minute vibrations which would be otherwise so evanescent in their action as to be scarcely appreciable. There are many different degrees and power of hearing. Helmholtz states its entire range to embrace eleven octaves, and the practical range of musical sounds to be embraced between forty and 4,000 vibrations a second. It is a well-known fact that all people do not possess musical ears, and that some are unable to distinguish one tune from another. A plausible way of accounting for this would be by some deficiency in Cortis fibres; but this is negatived by the fact that authentic cases are detailed where patients affected by violent fevers in which the brain became engaged, on recovery found that from not being able previously to distinguish a note of music, they now possessed a perfectly musical organ. No doubt all these fibres have each their minute nervous filament, and it may be reasonably supposed that the irritation of the nervous centre communicated vitality to its dormant terminal extremities. This, however, involves many speculative theories which, when sifted well, no doubt, prove of practical value; but they are too crude to at present enter upon. My endeavour has been in a brief manner to trace the sense of hearing from the mere perception of sound, capable by animals having only a rudimentary organ, through the different classes of creation to perfect man. We see that the whole action which brings the sense into play, is one of physical force, and we must recognise how essential it is to the perfect action of the sense of hearing to retain in all its perfect efficiency that agency, by which these physical impressions are imparted to the auditory nerve. Those specious arguments which are used to prove that the auricle is useless, and those which deserve far greater condemnation in their endeavour to show that the membrane of the tympanum is nearly, if not, altogether valueless, are dangerous sophisms calculated to mislead the practitioner who, not having time to closely investigate a particular subject adopts the opinions, and imitates the practice of those who, from their special application to the subject, are looked upon as pioneers who may be safely followed. I believe it to be fallacious reasoning and faulty surgery that, because there are some few cases in which the loss of heavy power has been proved to be very slight, though there was considerable loss of structure in the membrane of the tympanum, that this membrane should so frequently be perforated by the surgeon's knife for the sake of experimental practice; the argument sometimes used in support of the operation, that this membrane is gifted with superlative powers of reparation is a mere begging of the question. It resolves itself into a simple query and reply. Is the vibratory power of this membrane affected by an aperture in it, or by the exudation of plastic-lymph, which must attend the process of healing after an incision, necessarily leaving a cicatrix? I assert it is not so efficient a medium for the transmission of physical impressions to the nerve, as it would be in its normal state entire, and without a cicatrix. There are certain cases, particularly in scarlatina, where the perforation of this membrane is attended with the happiest results, both in its immediate effect in mitigating the head symptoms, and in obviating the after consequences of ulceration. But, I believe, with the other appliances at our disposal, puncture of the membrana tympani for treatment of the cavity of the tympanum is contrary to the principles of conservative surgery.

LATERAL LITHOTOMY. (a)

(Under the care of DR. LAFFAN.)

Medical Officer to the Union Hospital, Cashel.

J. C., æt. 6½ years, was brought to me in September last, complaining of pain and undue frequency in making water.

From his previous history it appeared that he was healthy up to the age of 1½ years, when having been put to sleep in a damp bed, he was noticed to have become ill, and his abdomen to be tumid and painful. This swellling lasted off and on for about twelve months, at the end of which time the symptoms now complained of first attracted notice. There were frequent calls to pass water, which came in drops, and with such violent paroxysms of pain as to make him look like one possessed. As time wore on these symptoms increased in severity, sometimes however they intermitted for a month or two, and once for six months, and to such an extent as to lead the little patient's friends for the time to believe that he had shaken off his terrible ailment. While his sufferings were aggravated by change of weather, they were (curious fact) on the other hand much ameliorated by active exercise. He was in general better while up than while in bed. All this time his appetite and general health were excellent, his bowels were regular, and his sleep was good, save when he was attacked. Further inquiry elicited that the pain preceded the act of micturition, that the urine was clouded, and that no blood had at any time been noticed in it. On testing the urine it was found to be of alkaline reaction, to contain large quantities of mucus and phosphates, and to present traces of albumen. These symptoms pointing in the direction of a calculus, Thomson's sound was passed with the result of establishing the presence of at least one stone. The instrument was again used on the succeeding day, and on this occasion the existence of three calculi was made out, and an approximation arrived at as to their size.

(a) Read before the Surgical Society of Ireland.

The necessity for an operation being clear, and lateral lithotomy being indicated, the little patient was subjected for a few days to the usual preparatory treatment. On the 16th September, his bowels having been previously opened by an enema, he was secured in the usual position, and chloroform administered by my Hospital Dresser, Mr. W. Hourigan. A free incision was made in the superficial parts, and this was carried deep enough internally to allow the knife at once to come in contact with the groove in the staff. A small vessel was wounded, but the bleeding was almost *nil.* A limited cut was made in the left lobe of the prostate, and more room was found by slightly notching the right side of that organ with the probe pointed bistoury. The bladder was reached with ease. Some difficulty was experienced in seizing the calculi owing to the escape of two of them into an unusually well developed *basfond*, and of the third into the portion of the viscus above the pubes. This difficulty was overcome by pressing on the *basfond* through the rectum, and on the superior portion through the abdominal parietes. The three calculi having been now one by one extracted, search was made for any more which might be present. The organ was then carefully washed out; the tube inserted, and the patient untied and removed to bed. A hot poultice was ordered to be laid over the abdomen and renewed every hour, and mucilaginous drinks and small doses of Dover's powder directed. He showed no unfavourable symptoms during the rest of the day. Next morning I was informed that he had slept well, that he had taken all his drinks, and that he felt no pain anywhere save in the wound. His pulse was a hundred and twenty, and the water had passed entirely through the tube.

He continued to go on favourably in every way. On the night of the 17th the urine came through the urethra for some six hours. On the morning of the 18th the patient anticipated me by removing the tube, and the water now came entirely for five days through the wound. It then came through wound and urethra up to the 4th October, after which it passed in drops only through the wound. All this time matters progressed so well as to leave little to note. By the 24th October the urine ceased to come even in drops through the wound, which was now nearly closed. The urine continuing to deposit phosphates and mucus in quantity, an injection containing acetic acid was thrown into the bladder, and nitric acid and Pareira Brava exhibited internally. Under the influence of this treatment the urine regained after a few days its normal character and reaction. All traces of mucus and phosphates have now disappeared, the wound is entirely healed, and the child restored to perfect health.

Two of the calculi are now exhibited to the Society. I am indebted to my talented friend and former pupil Mr. Thomas MacKenna of the Catholic University School of Medicine for having made a complete analysis of the third.

He informs me that it consisted exclusively of urate of ammonium. If we might hazard a speculation from the facts before us as to the cause of these lithic deposits, we might attribute them to the suppression of the cutaneous and renal secretions which probably followed from the damp bed. This would tally with the view of Dr. Marcet mentioned in Golding Bird's "Treatise on Urinary Deposits." The phosphatic deposits on the other hand were probably derived, not from any constitutional lesion, but were the result of local vesical irritation.

◆

Baby Farming :—At a meeting held last week at the offices of Mr. Manning, coroner of the Queen's Household, in Great George street, Westminster, it was resolved to petition in favour of a compulsory registration of all births and deaths within a limited period of their occurrence, and of licensing and inspecting houses in which children are taken in to nurse.

Hospital Reports.

KING'S COLLEGE HOSPITAL.

Removal of Fibrous Tumour from the Side of Face.

(Under the care of SIR WM. FERGUSSON.)

SIR WILLIAM removed a large fibrous tumour from a man's face by the process he has for some time past advocated, and one which he fully believed to be the correct method, notwithstanding there were still many surgeons who obstinately persisted to admit the correctness of Sir William's views.

The operator was of opinion that the knife should be used as little as possible in cases of this kind, and that such tumours should be lifted out as it were of their sheath or sac by the aid of the elevator and the operator's fingers, and he felt certain that with practice and the recognition of healthy from diseased structure, that this method of removing tumours would be found to be not only easy but of the highest advantage to the patient. Again, Sir William said, look at the dangers that were avoided by this method, the bleeding (which by the old, and as Sir William believed, wrong method), not only was it great, but in some instances fatal, whereas, as the class had seen, in the present instance, it was so slight as to be scarcely worth noticing. Again, when a large extent of surface was cut, as there would have been in the present instance, had not pathology taught us to recognise a simple fibrous tumour such as the one before the class from the so-called parotid of the older school of pathology, nerves would have been divided, and on more than one occasion the portio dura had been divided. Such a serious complication as this could never happen by the operative procedure he now advocated.

METROPOLITAN FREE HOSPITAL.

(Under DR. C. DRYSDALE, reported by MR. WM. KIPLING.)

Clinical Uses of Faradisation.

Previous History.—Joseph Johnson, æt. 45, occupation a baker, never had any serious illness. A year ago a sack of flour fell on his back, he was bruised a good deal at the time, and has had pains there more or less ever since.

Present attack.—Came on last May with pains in his arms, the left one worst, followed in a day or two by inability to hold anything, no numbness or diminished sensation; his legs were affected the same way, so that he could not walk unless he was able to hold on to something; never had any fits or any difficulty in micturition or defæcation, he has not been able to follow his occupation.

November 4th.—Arms feel heavy; a little numbness in them; no pain or coldness; can only hold small things; sensation good; can raise his arms but not to meet above the head; on his left side when his wrist drops, he cannot raise it; never had anything to do with lead; can walk pretty well for a short distance, but if he goes very far his legs ache at the back; cannot stand on one leg without support, the left being the worst, they sometimes swell a little; has occasional headache; all the five senses good; appetite good; bowels confined; pulse 64; tongue clean. Ordered to have the muscles of legs and arms galvanised every morning.

℞ Tinct. nux vomica, ♏v.;
Aquæ, ℥j. t.d.s.

November 10th.—The different groups of muscles in arms and legs act well under the above treatment, he can now raise his left wrist very well; pronation and supination better; he can stand better on his legs, but not very firm on them yet; feels better since admission.

November 20th.—Says he feels greatly better; he can now lift good sized objects, as chairs, &c., very well; he can stand on either leg now, and has more command over them; can now cross them, which he could never do before. As he thought he was able to follow his employment he was discharged, to come occasionally as an out-patient.

Peter McFarlane, æt. 35, occupation a sailor.

Previous History.—Had a chancre ten years ago followed by a rash and sore throat. Had an attack of scurvy and dysentery eight years ago. Troubled with ague a year ago.

Present Attack.—Came on last June, when off the coast of Java, due to sleeping on deck all night, as he went to sleep well and awoke with the paralysis, he attended the Singapore Hospital for a couple of weeks.

State on Admittance, September 22nd.—Patient is rather emaciated; there is distinct paralysis of the facial nerve on the right side; patient cannot frown on the affected side or close his eyelids; the buccinator muscle lies flaccid, and food lodges between his mouth and gums, he cannot blow properly, the air escaping at the right angle of the mouth which is drawn down below its usual level, whilst the left one is drawn upwards and to the left; pupils and tongue normal; pulse 80; bowels regular; sensation diminished on affected side.

Ordered Potass. iodide, gr. v.;
Tinct. nux vomica, ♏v.;
Aqua, ℥j. t.d.s.

To have the muscles on the side of face affected, galvanized twice a day.

October 17th.—Patient has continued under the above treatment, and is much benefited by it, he can close his eyelids better; the muscles of face are more sensitive, so that he does not require so strong a current as at first; he has had the side of his neck behind his ear occasionally blistered with the liquor epispasticus.

℞ Potass. iod. gr. x.;
Aqua, ℥j. t.d.s.

November 3rd.—Has greatly improved since admission in every respect, he has increased in weight; can now completely close his right eyelids; the mouth is not so deformed; he can blow better, though air still escapes from the angle of the mouth when he does so; food still lodges between his cheek and gums, but not so bad as when he first came in, otherwise he is in very good health, and left to day as he wants to go to sea again.

December 12th.—Seen again to day, when he can almost close his eye, and seems greatly improved in his general appearance, and the deformity is now scarcely perceptible.

A CASE OF COMPLETE RECOVERY AFTER REMOVAL OF THE BODY OF A CERVICAL VERTEBRA.

By William Ogle, M.D.,
Assistant-Physician to, and Lecturer on Physiology at, St. George's Hospital.

In this paper a case was narrated of which the following were the chief points:—A man, after suffering for some months from sore throat, became out-patient at St. George's Hospital. It was found on examination that some bone was exposed at the back of the pharynx; but the patient suffered so little inconvenience from this that he could not be persuaded to become in-patient. The man's attention having been directed to the exposed bone, he got into the habit of fidgeting it about with his fingers, and at last loosened and removed it himself. On maceration, the piece thus removed was found to consist of the antrum of one of the cervical vertebræ and a small portion of the antrum of a second one. After remaining for some months out-patient, the man was persuaded to enter the hospital. He was placed on his back, and his head fixed; and remained in this position six months. During this time he expectorated numerous spicules of bone, and what appeared to be, portions of fibro cartilage. The lesion eventually healed completely; and the man at the present time—two years since the lesion—is able to occupy himself with the heaviest farm-labour, and to amuse himself with field-sports. There is no visible deformity of the neck, nor any other sign of what has occurred except a slight stiffness in rotating the head. The piece of bone was exhibited.

CASE OF TRACHEOTOMY IN WHICH THE TUBE, HAVING BECOME DETACHED FROM ITS SHIELD, ESCAPED INTO THE TRACHEA, AND WAS REMOVED BY A SECOND OPERATION FOURTEEN MONTHS AFTERWARDS.

By John W. Ogle, M.D., F.R.C.P.,
Physician to St. George's Hospital;
AND
Henry Lee, F.R.C.S.,
Surgeon to St. George's Hospital.

The patient, a man æt. 32, had been the subject of typhus fever in 1865. He recovered, but never afterwards felt thoroughly well, and about a year subsequently had an attack of laryngitis and bronchitis. Tracheotomy was performed, and the patient continued to wear the tracheotomy tube for three years, when the shield became detached. It was improperly reunited to the canula, and in another year's time it was again detached, and on this occasion the canula slipped into the trachea. A few weeks after this the patient was placed under Dr. Ogle's care in St. George's Hospital, suffering from great dyspnœa, and having the sensation as if the tube were situated on a level with the upper part of the sternum. Auscultation failed to help in deciding the position of the tube, and the patient refused to have chloroform administered with the view of search being made for it. He then left the hospital (September, 1870), and continued to go about, suffering from dyspnœa and irritation about the windpipe, until his symptoms became more urgent, and he was obliged to come to the hospital again on the 5th of November last. He said "he had coughed the tube up into the throat, and could feel it there," No time was lost. The patient was at once placed under the influence of chloroform, and as he lay upon his back tracheotomy was a second time performed, and two eroded portions of metal were taken by means of curved forceps from the trachea. The pieces were almost the length of a tracheotomy tube, and gave origin to the idea that the original tube had been bivalved. This, however, upon enquiry turned out not to have been the case. The pieces of metal had been eroded into their present shape while in the trachea. The pieces were shown to the Society.

A second case, which some years ago had occurred under the observation of Mr. Lee, was related. In this instance a boy had swallowed a fourpenny.piece. This was expelled without operation through the glottis during a fit of vomiting. In the observations made attention was drawn to the different modes of treatment likely to be required in cases of smooth or round bodies in the trachea, as in the last mentioned case, and cases in which pointed or rough bodies had to be removed as in the instance first recorded.

SCOTLAND.

EDINBURGH.

Royal Infirmary.—The adjourned meeting of contributors was held on the 15th. The report of the committee on the manager's report which recommended the deletion of the third resolution proposed by the managers, excluding firms from voting was adopted by a majority of five. The meeting broke up before a vote was taken on the legality of Professor Masson's motion as adopted at the former meeting. The exclusion of firms from voting, would, it is understood, have an injurious effect on the interests of the lady students; in the meantime an interdict has been served prohibiting the chairman of the meeting of contributors receiving votes of firms or companies.

The epidemic of small-pox continues with great severity in Edinburgh and Leith, but it is assuming a milder form.

MEDICAL HONOURS.

As almost alone among the medical journals we have boldly stood by the rights of the profession to the Peerage as well as to all other honours and every kind of rank, and that, too, when the *Times*, in an article otherwise freely appreciating the profession, spoke against hereditary honours, and especially the Peerage, being conferred for personal service, we hail with gratification the powerful ally of the profession that has appeared in the facile pen of Charles Lever. This distinguished writer has addressed a letter to the *Pall Mall Gazette*, which was published in that journal just as our last impression was posted. To ask any reader's attention to the words of so popular an author is quite superfluous, and although we have much to say respecting the honours due to the profession, we only too gladly stand aside to make room for Charles Lever's plea on our behalf. His letter to the *Pall Mall* is as follows:—

SIR,—At a very remote corner of Europe I have just read a leader in the *Times* on the question of the rewards that might with propriety be extended to eminent medical men, and the reasons which, according to the writer's opinion, should exclude them from the greatest reward of all—the Peerage. The *Times* argues the question fairly enough. There is no more than truth in saying, however vague and mysterious the significance may be, that "this is not the moment in our history in which any extension of the feudal principle would be particularly well received, and that the hereditary principle would incur a certain shock at the innovation." Less fairly, the writer asserts that we have no security that "the son of the doctor would be himself a doctor, or eminent, if he were one"; for surely we enjoy no similar security with regard to those persons whose distinguished services have raised them to the Peerage. In elevating the great soldier, the diplomatist, or the lawyer to the Upper House, do we stipulate what the eldest son of any of them may be? or do we look for any other security than the likelihood that the man whose merits have raised him to the highest rewards of the State will, in his intense conviction as to the qualities by which his own success has been achieved, so educate and train his son as to fit him for an exalted station, and enable him, so to say, to justify the advancement of his house? I do not know that we have any other guarantee than this, nor do I see that we need one.

That the eminent physician might not have adequate means to sustain his increase of rank, is no more than might be said of the successful barrister; and of course selection in either case would be influenced by this circumstance. The rewards of Medicine of late years have, however, not fallen very far short of those of the Bar. Sir Astley Cooper's income was rated at £20,000 per annum, and Sir Henry Halford unquestionably left behind him a fortune not unequal to the dignity of the Peerage. Many of the law lords have hesitated as to accepting titles which seem to imply a corresponding wealth; but, once in the Upper House, there has never been heard in any section of society a word that could connect their influence with or measure it by the extent of their fortunes. So would it be with the physician. He could not compete as a territorial magnate with many around him; but his position would not be less dignified, nor his words carry less weight.

I own that I am anxious to see some share of the high honours of the State bestowed upon a class which, whether simply regarded as numbering among them some of the ablest thinkers and writers of the age, or conferring more gratuitous services on the world than every other rank and condition together, are still less recognised than any other. I see with satisfaction the advancement of the great soldier, the gifted diplomatist, or the learned lawyer to the rank of our hereditary nobles. I can admit a certain fitness in accepting great wealth as a qualification, if great wealth represents industry; but it is in the very diversity of these men's pursuits, whether as lawyers, bankers, or millowners, that I recognise a greater gain to the wisdom of Parliament than any distinct course of training could possibly confer on any one section of mankind. When Figaro said, "All the world was wiser than any one," he uttered a great truth, and it is in this aggregate of opinion that the highest wisdom is sure to be found. If, therefore, I am very desirous that the doctors should have their fair share of the honours of the State, my eagerness is sharpened by remembering how self-rewarding your generosity will be. Among all the trained and polished intellects you assemble in the Upper House you have not got that special form of mind that distinguishes the doctor. You have not got a man whose daily life and labour is passed between the deepest problems of science and the practical working of the great truths he has been considering. In knowledge of his fellow-men he is without a rival. His study of temperament is a study of character; and this not in one class or condition, but in every walk and rank—from the palace to the hovel. He is the one man with whom no fallacy can succeed that assumes to say what men in this or that station might do or think, for he knows them all. Occasions now and then arise in which it would be an inestimable benefit to legislation to know the spirit and temper of the people at large—to learn how, apart from the language of the press, and in sections where the press is less of an influence, men think and speak of the topics of the hour. The fluctuations of public opinion, the steps by which men cool in ardour about this or become hotly impassioned as to that other, those strange revulsions of sentiment which nations feel like individuals—witness, for instance, the singular sense of sympathy in favour of France that came over England in the last months of the war,—these are not only more quickly noted by the doctor, but he is better able to gauge their strength and depth, and argue as to their durability. To him these signs are purely symptomatic, and he measures them by the habits of his art. The hysterical bursts of national passion that mean nothing more serious than a manifestation; the taste for revolution which simulates the spread of epidemical disease, and yet contains no real germ of malady;—all these he is familiar with; and which of you, I would ask, knows them as he does? Is it you, my lord duke, or is it the noble lord on the woolsack? or could the right reverend bench ever depute one of their body who could pit his knowledge of his fellow-men against this ubiquitous comforter, who now whispers his words of warning to Royalty, now holds the cup to the famished child in fever?

To the great social questions which latterly have occupied a large share of parliamentary notice, who is there can contribute such important and varied knowledge as the doctor? The health of towns, the maladies of special trades, the influences that dispose to epidemics, the sanitary measures that limits the spread of infectious disorders, the principles that should be held in view in all cottages or houses for the poor, the character of the water supply, and the class of diseases which are fostered by neglect of due attention to these details; the character of epidemics generally, as applicable to such visitations as cattle plague, the means to arrest it; the consideration of the quarantine laws, and what benefits modern science could contribute towards their amelioration; the health of emigrants, and the modes to promote it: these are but a part, and a small part, of the subjects on which the physician could speak with the authority of a special study; for he alone among educated men has, by making animal chemistry, physiology, and anatomy a part of his education, fitted himself to discuss these themes with a knowledge of first principles that no desultory reading or dilettanti acquirement could possibly compete with. I say it advisedly, it is a class of mind that you have not got among you, and it is an order of intellect that would contribute largely to your enlightenment. The investigating spirit that is not deterred by chance disappointment nor over-confident by chance success; the watchfulness that does not overlook small circumstances, that understands what measure of bearing they possess on larger conditions; the patient habit of inquiry, which, knowing that effects must have their cause, is ever watchful to detect the meaning of this or that change in the state of the country: these are no small contributions to bring to the assembled wisdom of the State. I find it difficult not to quote the names of a number of our distinguished contemporaries—names many of them as well known to literature as to medicine—and ask you what body of legislators would not benefit by the addition of these to their number? Is it by the unobtrusive character of the services they daily render you that you can justify your neglect of them? or do you imagine that you have acquitted your debt to them by according the moneyed value of their labours? Not, indeed, that you do, or that you could do this; for there is not any sum that could recompense services which make demand not only on the acquirement of years of patient toil and drudgery, but of intellectual efforts strung to the highest tension, and accompanied by continual exposure to contagious malady and fever of every form of intensity. I am curious to know what quality there is in the legal mind that has established the conventional precedence over the medical, or why the highest honours of the State that are open to the one should be denied to the other? It can scarcely be said that it is the higher importance that attaches to a man's belongings than to his existence; since, in the very leader I have referred to, the writer says that before a man can plead or be a witness, he must at least be alive. It can even as little be that lawyers have done as much for the general knowledge and instruction of their fellow-men as the doctors. The names of the two orders in literature would soon dispel the pretension. Will it be said that the services of the lawyer to the State are more calculated to exercise a greater and more enduring influence than those of the doctor? If this ground be taken, I would reply that the discoveries of Charles Bell—discoveries which even among educated Englishmen are not known to one person in three—are of higher import and destined to greater consequences for the benefit of mankind than all that has been written by Westminster Hall for the last two centuries.

Yours, &c.,
CHARLES LEVER.

◆

Notes on Current Topics.

Royal Free Hospital.

It is rumoured that the medical staff and the weekly board have been crossing swords with respect to the medical arrangements of the hospital. The medical staff, although having the power of recommending the resident medical officers for appointment, ultimately have no control over them. The senior resident medical officer having resigned, the weekly board has appealed to the medical staff for recommendation as to the status and duties of his successor. The medical staff has made some recommendations, which the weekly board has thrown out, and has advertised for a successor, without affording the medical staff any opportunity for appeal. It is to be hoped that the weekly board will re-consider their decision, since it is clear that the medical officers, who are entirely honorary, can have but one desire, that is the welfare of the hospital. We fear that there must be some traitor in the camp, or surely the weekly board would not act thus.

Prosecution for Illicit Practice.

Mr. John A. Forbes, chemist, Aberdeen, recently prosecuted several of the medical swindlers established in that city. John Boyd was charged before Sheriff Thomson with having falsely and wilfully pretended to be a Doctor of Medicine. He had advertised himself as such in a local paper, and his name appeared in the "Aberdeen Directory" as John H. Boyd, M.D. He was fined £10, and two guineas expenses. Frederick Adair was also tried. His address was the same as—and we therefore presume that he was a partner with—the last-named defendant. In this case, too, the complaint was founded on an advertisement. Sheriff Smith decided that as it had not been proved that the advertisement was inserted by the authority of the respondent, he therefore found the charge not proven, and expenses were allowed to the respondent. Mr. J. A. Forbes also prosecuted John Chadwick, 21 Lodge Walk, for the unauthorised use of the title M.B. The defence was that the letters M.B. and L.V.M. meant medical botanist and licensed vendor of medicine. The Sheriff considered that if a man called himself M.B. he must certainly be understood to hold himself out to the world as possessing the degree of Bachelor of Medicine, and therefore likely to deceive the public as to his professional abilities. The respondent was fined £10, with £3 3s. expenses.

Injection of Ammonia as an Antidote to Chloroform Poisoning.

The efficacy of this method has been tried recently in Melbourne with very encouraging results. A person while under the influence of liquor drank an ounce of chloroform in two doses, and became immediately insensible almost immediately. An emetic of salt and water, which was poured down his throat without delay, caused him to vomit. The injection of liquor ammoniæ into the veins was decided upon. Half a drachm of liquid ammonia was injected into a vein in the arm, the strength of the injection being one part of ammonia to two parts of water. The good effect upon the pulse was rapid and marked, and after an interval of twenty-five minutes, another half-drachm was injected. The improvement increasing, a third injection was made after another interval of twenty-five minutes. After three quarters of an hour another half-drachm of ammonia was injected, bringing the total amount of *antidote* introduced into the blood to two drachms. The deceased regained consciousness about midnight, and, with the sanction of his medical attendant, was removed between seven and eight next morning from a house of ill-repute where he had been staying to his own residence. The deceased subsequently complained of weakness, and expired twenty-four hours afterwards.

The Prince's Physicians.

So Dr. Gull is to have a baronetcy, and as Sir W. Jenner already has that rank, he is to have a K.C.B. in addition. Surely he ought to have something more. If the Government dare not follow Charles Lever's advice, and bring a physician into the House of Peers, they might have surely done a little more than this. The G. C. B. would not be so very much, but perhaps the K. is intended to lead to that. Why do they not make Jenner a Privy Councillor, where his services would be invaluable ?

And what is to be given to Dr. Lowe ? What to the usual attendants of the Prince and Princess ?

The Lessons of the Prince's Illness.

DR. BALTHAZAR FOSTER has published a lecture on the prevention of disease, which he delivered in reference to the Prince's illness. It is a pamphlet we should be glad to see widely circulated. If the people would only learn and practice the lessons so often inculcated by their natural guardians in sanitary matters, the public health would be much better than it is. We have not come to the same conclusion as Dr. Foster in our articles on the origin of the Prince's disease, but we can with confidence recommend his pamphlet as eminently suited to give valuable instruction to the public, and as one which ought to be extensively read.

Dr. Arnt on Electricity in Insanity.

DR. ARNT (*Die Elect. in Psch.*, Berlin, 1871,) demonstrates the efficacy of electricity in the treatment of the insane : the induced current excites the nerve centres and some patients revive under its influence and commence to occupy themselves. The author prefers to faradise the extremities, and to excite the phrenic nerves : at first the strongest current is scarcely noticed, but soon the reaction occurs, and then the intensity must be lessened. The galvanic current is applied to the spinal cord with one rheophose and to the skin, &c., with the other. A lady, æt. 57, suffered in 1863 profound grief after which she became irascible, and, after a great attack of sweating, religious mania showed itself, with attempts at suicide ; she grew better, but relapsed in 1865, and in 1868 was so maniacal that a wound on the arm could only be treated by administering chloroform. She was well nourished, with dry skin, brittle epidermis, right pupil dilated and left contracted, respirations 16, pulse 80, rigidity of the lower limbs, tremor of the arm and tongue, mimic contractions ; she was paretic and would let a cup fall from her hand ; at one time she would not eat, at another ravenous ; embarrassed in speech, with pains in various parts of the body, especially in the occiput ; nevertheless, can sleep by means of morphia. In January some boils appeared and she was better. In February relapsed, and believed herself to be pursued ; general tremor, with ears and face pallid. Warm baths 32° R. were given and calmed her ; the pupils were contracted, the tremor ceased, the face became coloured, and the pulse was 80. In March there was rigidity of the nape again, humming noises in the ears, and pains over the body ; she accused herself of imaginary crimes. Iron and quinine. The author shrewdly suspected that all these symptoms set out from the nerve centres and not from the sympathetic ; the embarrassment of speech, the weariness, and trembling in the arms arose from the perturbed innervation of the cervical and brachial plexuses ; but the abnormal sensations must have origin in the centres of sensation, or posterior cords. Thus in the thought that by diminishing the excitability to galvanism would moderate the pathological excitability, he decided to try galvanism. On the 17th of March he employed an apparatus of 16 elements, applying the anode below the occipital protuberance, and the cathode to the back, in the neighbourhood of the vertebral column. The patient felt no sensation until 26 elements were employed. When 26 were used there was a slight sensation at the cathode. The right pupil which at first was more dilated became afterwards equal to the left. In the evening she felt better ; the pupils were equal. On the 18th and 19th she had for the first time tranquil sleep. The application was made for half-a-minute at a time. This continued for a month, and on the 9th of May she was perfectly cured. A boy also was cured in the same way, whose insanity came on after chorea. Faradisation of the arms and shoulders, caused dilatation of the pupil.

Infectious Diseases.

IN consequence of a resolution passed at a Meeting of the Committee of Works held on Tuesday, in an amended report from Dr. Aldis it is remarked that our Sanitary Acts of Parliament are in a very confused state, but there is reason to hope that the Government will endeavour, in the next Session of Parliament, to remedy an evil deeply affecting the public health. Dr. Aldis suggests—1. That the Medical Department of the Local Government Board be asked to empower the Vestry to refer to a Committee, the authority to carry out such sections of the Metropolis Local Management Acts as relate to the abatement and removal of nuisances, in the same way as they are empowered to refer the carrying out of the Nuisances Removal Acts by the 5th Section of the 18 and 19 Vict., cap. 121. 2. That with a view to steps being taken to prevent the spreading of infectious diseases, every medical practitioner should immediately report such cases, occurring in private or public practice, to the Medical Officer of Health of his district. 3. The 23rd Section of the Sanitary Act stipulates that the Nuisance Authority in each district *may* provide a proper place, with means of disinfection. The word "shall" should be used for "may," when necessary, adding also a power to destroy infected articles, where necessary. 4. The 25th section of the same Act provides a penalty on a person suffering from an infectious disorder entering a public conveyance without notifying to the driver that he is so suffering. This clause should be so modified as to impose the duty and penalty on the person *in charge* of the sick, when the latter is of tender years, or is incapacitated by bodily or mental disease. 5. That the Board of Guardians of every Parish or Union be compelled to provide suitable carriages for the removal of patients suffering from infectious diseases, and to give public notice where such carriages can be obtained. 6. The 27th and 28th sections should be made compulsory for the provision of mortuaries and reception houses. 7. In the 38th section the words "public place" should receive some addition so as to prevent persons, who have just recovered from infectious diseases from selling goods in their shops before they have been certified to be free from the risk of infection. 8. Persons should incur a penalty who wilfully conceal the existence of scarlet fever or small-pox.

Annual Report of the Surgeon General, United States Army, 1871.

We copy the following statement from the Surgeon General's report, which will be instructing and interesting to our readers :—

ARMY MEDICAL MUSEUM.

The Army Medical Museum continues to increase in the number and variety of specimens and its consequent usefulness. The number of specimens added during the year was 1,516, a present total of 15,018.

The number of visitors was over 15,000 during the year.

MEDICAL AND SURGICAL HISTORY OF THE WAR, &c.

Part First of the Medical and Surgical History of the War is near completion, and will be laid before Congress during its coming session, when it is hoped sufficient appropriation will be made to continue the publication of the remaining parts. Circular No. 4, a report upon barracks and hospitals, with a description of military posts throughout the United States, compiled by Assistant Surgeon J. S. Billings, U. S. Army; Circular No. 3, 1870, approved plans and specifi cations for hospital posts—also, a revised edition of the same (Circular No. 2, 1871), has been carefully revised and published during the year, and the Standard Supply Table of the Medical Department of the Army (Circular No. 1, 1871), has been carefully revised and published with a view to more rigid responsibility and greater efficiency.

Foreign Bodies in the Larynx.

In the discussion that followed the paper at the Royal Medical and Chirurgical Society, reported at p. 80, a number of interesting cases were mentioned :—

Mr. Curling, president, laid down as a rule of surgery that a foreign body in the trachea should always be extracted by operation.

Mr. Power, however, thought that smooth bodies, even of considerable size, might pass out by the natural passages, and mentioned the case of an Irishman who had a pebble in his larynx. By putting him on his face on a table, with his head low, and giving hm a slap on the back, the pebble was immediately ejected.

Mr. Couper mentioned a child who was brought to the London Hospital with a foreign body in the trachea. The surgeon who saw the case deferred operation, on account of the absence of urgent symptoms; but a paroxysm of dyspnœa came on in his absence, and Mr. Couper opened the trachea when death seemed impending. The foreign body was a bean which passed up and down behind the tracheal opening during the respiratory efforts. With some difficulty it was seized and extracted, but the patient died of pneumonia.

Mr. Holthouse showed the pieces of a tracheotomy tube which he had himself extracted, under circumstances similar to those detailed in the paper under discussion. He also mentioned having once permitted a pill to slip into his own larynx, and having ejected it immediately and without trouble.

Mr. Thomas Smith pointed out that children sometimes got acidulated drops into the trachea, and that these might be safely left to dissolve. Among other foreign substances that he had known to lie in the air-passages was a common dress-hook, the loops of which were directed downwards, while its bent extremity was hung upon one of the vocal cords.

Professor Alfred Swayne Taylor, M.D., F.R.S.

We are much concerned to hear that this eminent professor of Medical Jurisprudence and Practical Toxicology is labouring under a serious affection of his eyes, but trust ere long to learn that under skilful surgical treatment, the danger may be averted. The learned professor, whose name and works are universal, we are sure, will have the sympathy of the whole profession.

Army Medical Department.

Deputy Inspector-General T. Crawford, M.D., has been ordered to India, and has therefore given over the duties of the medical branch of the department. He will probably be succeeded by Deputy Inspector-General Massey, M.D., C.B., at present at the head of the sanitary branch. Deputy Inspector-General J. E. Carte is about to retire from the service. Surgeon Hoysted embarked for Malta on the 10th inst. to join the 52nd Foot. Staff Assistant-Surgeon Fawcett sails on the 18th inst. for Madras. Staff Assistant-Surgeon Hayden is on sick leave until April 22nd next.

According to the *Swiss Times*, the ladies at present attending the Zurich University constitute about one-tenth of all the matriculated students.

By the resignation of Dr. Goodfellow, there is a vacancy in the office of Physician to the Middlesex Hospital. There are other vacancies at Charing Cross Hospital.

An examination of candidates for forty appointments as Assistant-Surgeons in the Indian Medical Service will be held at Chelsea Hospital on Monday, the 12th of February, 1872.

The Lord Mayor presided on the 12th inst. at the Annual General Meeting of the Governors of the City of London Hospital for Diseases of the Chest, Victoria Park.

Mr. George Cooper, representative of the Apothecaries' Company, has resigned his seat in the General Medical Council. He was appointed on the death of Mr. Nussey in 1862.

The Committee of Management of the Northampton Lunatic Asylum have determined to receive a larger number of patients of the middle and upper classes of society, on payment of sums from 15s. per week and upwards, including all expenses except clothing and wine.

Gratitude being rare it is a pleasure to record that a lady, upon whom Dr. M'Intyre, of Odiham, operated for femoral hernia about twenty years ago, has recently died, and has left him as one of her executors, a legacy of £100, together with a bequest of £4,000, "in testimony of his great kindness and professional services."

We are sorry to hear that the Council of the Medical Society of London have prepared a congratulatory address to her Majesty the Queen and the Royal Family on the convalescence of His Royal Highness the Prince of Wales. If the Royal Family are to be bored with addresses from corporations, they might well be spared the infliction of them by learned societies.

Dr. Rose Cormack, of Paris, is to be knighted for his services to English subjects during the siege. We are glad of it. It is one more slight acknowledgment of public services by a medical man. But does it not suggest the names of many others who have laboured without recognition, and to whom we have lately several times referred.

The Brighton poisoning case has suggested a number of important questions of a medico-legal nature, and the conduct of counsel has induced Dr. Lockhart Robertson to publish the following memorandum drawn up before the trial :—

"Memorandum by Dr. Lockhart Robertson on the Case of Christiana Edmunds.

"The most marked symptom is the utter insensibility shown by the prisoner in the position she is placed in and the danger she runs. Her whole mind is centred on her letters to Dr. Beard, on his conduct in allowing his wife to read them after all that had passed between them, and on the horror she would feel, not at being tried for murder, but at these letters being read in her hearing in court. She further dwelt on her certain belief that Dr. Beard desired the death of his wife even by poison ; that, though too cautious to speak of it directly, he had hinted at it ; and that if so she knew he would marry her, &c. There was no emotion or anguish shown during my two searching examinations.

"From these facts I conclude that, while the prisoner has in the abstract without question the knowledge of right and wrong, and knows that to poison is to commit murder, she is so devoid of all sense of moral responsibility that she cannot be regarded as conscious of right and wrong, or morally responsible, in the sense in which other men are so. Her family history of insanity, epilepsy, idiotcy, &c., points to the insane temperament, and is consistent with the scientific deduction that the prisoner is morally insane, to use the familiar term.

"Counsel will judge how far a jury are likely to understand or discriminate between the intellectual soundness of the prisoner and the absence of all moral sense to guide and regulate her conduct, and on which alone any defence of insanity can rest. I am bound to add that, except in conjunction with the evidence furnished by the crime, I should not on my examination alone have felt justified in signing a certificate in lunacy.

"London, January 7."

Foreign Medical Literature.

CHEMISTRY OF ACONITINE.

(Translated for the Medical Press.)

M. Claude Bernard has presented a memoir to the *Académie des Sciences* by M. H. Duquesnel on L'Aconitine Cristallisée, a chemical study for the Barbier prize. He says that the active principle of Aconit. Napel. is a crystallisable alkaloid, to which he gives the name of Crystallised Aconitine in order to distinguish it from the substances of different origin known up to the present time under the name of Aconitine, the energy and therapeutic value of which vary with the productions. To prepare crystallised aconitine, aconite most suitably chosen and pulverised with the addition of 1-100th of tartaric acid, must be poured through very concentrated alcohol. The alcoholic liquors must then be distilled under cover from the air, and at a temperature not passing 60 degrees.

The extract is taken up again by water to precipitate all the fatty and resinous matters which the alcohol had brought in. The aqueous solution which holds all the aconitine in the state of acid tartrate is first shaken with ether, which takes away the colouring matters ; an addition of alkaline bicarbonate, until the cessation of effervescence sets the alkaloid at liberty. A new treatment by ether of this alkaline solution takes away the alkaloid which crystallises by the concentration of ethereal liquors, to which ether of petroleum has been added (light essence of petrole).

Crystallised aconitine presents itself under the form of colourless tablets, rhomboid or hexagonal, by a course of modifications which are produced on the sharp angles. It is azotised alkaloid that has for a formula :

$$C^{54}\ H^{40}\ AzO^{20}$$

corresponding to the following centesimal combination:

Carbon,	60·21 ;
Hydrogen,	7·44 ;
Azote,	2·61 ;
Oxygen,	29·74.
	100 00.

From 0° to 1001°, with or without water, heat has no immediate action on aconitine, nor on the salts which it forms with the mineral acids. Submitted to a temperature of 100° in contact with the air and its one extractive liquor, it has partly, and sometimes totally dissappeared in a short time. The chemical constitution of aconitine appears as if it ought to approach that of the glucosides, natural products frequently met with in the vegetable kingdom, and which have the property of doubling under the influence of certain agents, there is most often of proper ferments in glucose where an isomere, and of another part in one variable matter following the case. Thus might be explained the spontaneous alterations of certain pharmaceutical preparations of aconite which under determined influences lose all, or part of their properties. Crystallised aconitine is almost insoluble in water even at 100°. When a drop of acid is added to the water that holds it in suspension, it dissolves almost immediately at the ordinary temperature. It is not volatile, even beyond 100° ; beyond 1301° it decomposes and volatises in part. Precipitated from a saline solution by an alkali, it is amorphous, friable, white, and very light.

In this state it holds water of hydration, which it loses at 100° without changing its appearance. Aconitine is soluble in alcohol, ether, benzine, and especially chloroform ; insoluble in glycerine, oils of petroleum, heavy and light. It deviates to the left the mean of polarisation. Its reaction is feebly alkaline. It combines with acids, and forms easily with the greater part of the salts which crystallise. The azotate is remarkable for its easy preparation, and the volume of its crystals. In the presence of an excess of carbonic acid, it easily dissolves in water, but soon retakes its crystalline form, when the carbonic acid spontaneously separates from the liquor. Phosphoric acid, tannin, iodide of iodided potassium, and double iodide of mercury and of potassium are the most sensible reactives of aconitine; but, to characterise it absolutely, and to pronounce with certainty on its nature, we must have recourse to a physiological experiment.

The smallest quantity of this alkaloid or of one of its salts, or better still, of a pharmaceutical preparation of aconite, that is to say, containing aconitine, determines on the tongue at the end of some minutes a characteristic sensation of pricking and itching, analogous to that which the root of *pyrethrum* produces. Crystallised aconitine is one of the most active poisons of the vegetable kingdom. To seek for it in a case of poisoning, it is necessary to employ dialysis at first, then the process of Stas, surrounding oneself, in extracting the matters submitted to analysis, with all the precautions which a substance so alterable requires, a substance which can cause death in so feeble a dose.

NATIONAL FENCING.

By Edward Carcenac.

(Translated for the Medical Press, by B. Bertrand, Professor of Gymnastics to the Orthopædic Hospital).

Of all gymnastic exercises, fencing is not only the most active, but also the one which causes most shocks to all the system and which puts the muscles of the extremities the most in action.

Indeed the muscles of the thighs, legs and arms are almost always in a state of contraction, the movements of pronation and supination are very frequent in the arm which holds the foil, and the ligaments of the moveable articulations are obliged to extend and to comply with the efforts and the violent movements of the whole body.

In considering only this one aspect of this exercise one sees very well that it might supply medicine and surgery with a salutary method of strengthening the extremities, of rendering the movements of their articulations free, and of favouring more the circulations in the viscera, etc.

That is not all, fencing in giving to the body the postures necessary for guarding itself, gives it at the same time that natural, firm, and majestic attitude which is proper to the king of animals. Look at those professors of fencing, how stout, vigorous, well-formed, nimble and powerful they are! They look, as it were, like Hercules. It is in regiments of soldiers that this remark may be most commonly made. A newly-enlisted soldier hardly ever possesses this style, this attitude which is so much desired by colonels; they send him to the fencing room; he relishes it, and soon one sees that this athlete stands firmer upon his legs, that his gait is more elegant and warlike, and that his attitude, perhaps so ridiculous before, has become manlike, firm and determined. Does he not owe these advantages as much to the exercise of fencing as to the military exercise or to the practice of arms which keeps the body long at rest.

So fencing contributes more powerfully than any other exercise to increase of strength, to agility of the body, to loss of bad attitudes, and of certain deformities of the body.

Lastly, as this exercise excites the circulation and favours the perspiration, we think that it could be used by the medical profession with advantage in many cases.

Correspondence.

ON THE INFLUENCE OF ERGOT IN MIDWIFERY PRACTICE.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—Now that Drs. Sheil and Luther are at a wordy war with each other on some points of practice as regards a case of midwifery, allow me to make a remark or two on it. Dr. Luther seems to base his whole objections to Dr. Sheil's treatment, as he did not use the forceps and immediately deliver the second child if the head presented, or if it were a transverse presentation as he did turn and bring down the feet. Dr. L., I presume, is right on these points, but from Dr. S's. first communication (the 2nd November last), there does not appear any indication such as hæmorrhage, convulsions, &c., demanding prompt interference. In my humble opinion Dr. Luther appears to have overlooked the most serious part of the treatment, as regards the child, that is in the exhibition of the ergot. Now Dr. Sheil has stated, "I sat for two hours, &c., &c., notwithstanding repeated doses of ergot. I then left and three days after I was sent for, etc., etc." To me it seems an extraordinary proceeding to leave a woman with a foetus in utero labouring under the influence of *several doses of ergot for the space of three days.* I have looked into one of the most recent and, perhaps, best of works on Therapeutics, viz: Stillé's, where he quotes the words of Dr. Beatty, who says (in speaking of the length of time the ergot has been administered), "if it be short the child will be born alive, but if it be delayed two hours the child will be stillborn." Now, Sir, please allow me to report briefly by way of parallel to the above, a case which I think may throw some little light both on the therapeutic and toxic action of ergot. On the 23rd ult., at 12.30 a.m. I was called to attend Mrs. A, æt. 40, in her first confinement, who realises in an exact way the old adage of fat, fair and forty. I arrived a little after 1 a.m. at her house, which is about four miles from here. When I entered her room I found her lying on a feather tick, undressed, on the floor before a fire, I made a vaginal examination, and after some three or four minutes' search I discovered the os very high up in the hollow of sacrum and no larger than a three-penny piece. She said her sickness was severe and that the pains were strong. I told her to take them quietly for that it was a considerable time before she would be delivered. I then left saying I would visit her again between 10 and 11 same morning, which I did. At my second visit I found that much progress had not been made, for on examination os was not much larger than half a crown, rigid, but cool and moist, head presenting in first position. I now told her I could not remain and that in the meantime she might move about as much as she could. At 7 p.m. I visited her for the third time. She was now in same position as when I first saw her, and undressed. I examined, found os much more dilated, soft and cool. I remained now all night and directed her to move about occasionally. All this time there was vomiting now and then. I should have stated that the bowels were well acted on by castor oil before she took ill. At 11 p.m. the waters were discharged spontaneously and, after this, the pains died away gradually. I could now find the ear under right pubis and anterior lips of os down between head and it. On three or four occasions I put back lip of os, but down it would come again. Now I was feeling not quite at ease and was thinking to use the forceps, but that perineum was very narrow and rigid though the head was low down. I now ordered her to be undressed and put to bed, and some minutes after—exactly 10 to 3 a.m., I gave her *forty drops* of etherial tincture of ergot; pains soon returned, and with very much force, and in precisely *one hour and a half* afterwards she was delivered safely of a large, well developed male child, which was in a semi-asphyxiated state. Having cut the cord I made use of artificial respiration and frictions with no avail. I next put it into a cold and hot bath alternately, and it was only while in the hot bath that it gave the first sign of life by a scream. The child being now all right, I returned to the mother to remove placenta, which I could not though having used considerable traction on cord. I next introduced my hand into the uterus and found it firmly adhering to the fundus. After breaking down the adhesions placenta easily came away. When only a single and so small a dose of ergot, and in so short a time, produced such effects as in this case, I am grieved to think what it might not, or rather ought not, have produced in a case where *several doses* of it were administered, and so left for a space of *three* days! Perhaps it is all owing to idiosyncrasy?

I am yours, etc., etc.,

J. J. McKeogh, L.R.C.P. etc.

Thurles, 9th January, 1872.

P.S.—During my attendance on Mrs. A, I several times used the Stethoscope. J. J. McK.

◆

SMALL-POX CONTAGION AND INFECTION, HOW MEDICAL ATTENDANTS MAY REDUCE THE RISK OF BECOMING CARRIERS THEREOF.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir, 1.—Revaccinate at the onset of each epidemic of small-pox until characteristic vesicles cease to be produced thereby.

2.—Attend to general health, avoid prolonged fasting.

3.—Either drive in an open vehicle or walk a short distance before entering a closed conveyance.

4.—Wear overcoat in sick chamber, placing woollen gloves or scarf in pocket thereof. Where possible keep head covered.

5.—Avoid actual contact with the patient.

(a).—Carry an old newspaper. Before feeling the pulse: order a teacup-ful of water, add a teaspoonful of Condy's fluid, dip a suitable portion of the paper therein, apply it to the radial half of the wrist. [Rinse fingers in the fluid and dry them on own linen.] Resort to a similar plan, slightly modified, in Stethoscopic Examinations; 'ere viewing the throat let the patient wash out the mouth with disinfecting fluid.

(b).—Brief visits; necessary orders given outside; printed directions recommended.

Respectfully yours,

R. Hanslip Sers, M.R.C.S.

Epperstone, January 15, 1872.

◆

Inventions.

VULCANITE URINOMETERS.

Messrs. Blaise and Co. (successors to Savigny and Co.), of 67 James's street, S. W., have introduced vulcanite in the manufacture of Urinometers in the place of metal or glass; and from the fact of this material taking its gravity so much quicker, and with the greatest precision, we are convinced these instruments will supersede the old kind. Metal ones corrode, and glass ones are liable to breakage, but the vulcanite ones from the mode of their manufacture can always be depended upon. Messrs. Blaise also make hydrometers, saccharometers, &c., of the same material. Having tried the Urinometers we confidently recommend them as much superior to those in common use.

◆

Medical News.

Dover and Portsmouth respectively are already beginning to take measures for securing their selection by the military authorities as the locality of the usual Easter Monday volunteer review.

Habitual Drunkards.—Dr. Dalrymple, the member for Bath, has again addressed his constituents. He proposed to send the habitual drunkard to a reformatory, where he might learn that he could live without getting drunk, and where he would earn money enough to pay his cost while there, so that he might not be a burden to society. Where, he asked, would they find one word in that of "robbing a man of his beer?" or of "clapping a chap away because he had had a drop too much?" He had visited the inebriate asylums in America and Canada, where he found in many of these institutions over one-third, and in some one-half, of the inmates had been permanently cured, and a great many more had been benefited. While on the other side of the Atlantic, he heard that the Permissive Bill would not work; that in districts where it was enforced, with few exceptions, it was found not to prevent drunkenness, while the surreptitious and clandestine use and sale of liquors went on to a formidable extent.

Australian Meat Preserving.—The *Melbourne Argus* states that the news by the last mail of a revival of the demand for Australian meats in the European market will considerably brighten the prospects of the preserving companies in the colony of Victoria. It adds that probably if the news had arrived a mail sooner the two companies which had recently relinquished business after scarcely twelve months' career would not have found so much difficulty as they did in obtaining the requisite support to carry them over the period of slackness which temporarily paralysed them and eventually obliged them to succumb. The *Argus* adds that the misfortunes which have fallen on two or three companies have not, however, daunted others which have lately been set on foot upon an apparently sounder basis. Several new companies are announced, and some of them are already at work.

The last official return of the number of paupers in the metropolitan workhouses was 122,597, of whom 87,107 received out-door relief. Compared with the corresponding week in the years 1871, 1870, and 1869, these figures show a decrease of [illegible], 34,257, and 26.562 respectively.

Pure Water.—I am glad to find the subject of boiler water referred to in your columns of the 6th inst.; but quite apart from the contamination of water in the boiler cistern from other sources—a condition which no doubt is more common than is generally suspected—the water that is continually simmering in a boiler at the side of the kitchen grate, cannot be fit for drinking purposes—for making tea, coffee, etc., for instance, nor even for culinary use, as in boiling vegetables, or making soup stock, and so forth. Even if the water be perfectly pure when it enters the boiler, which, however, is very questionable, and though the contents of the boiler may be renewed during the day as the water is drawn off for use, yet it loses some of its best qualities by evaporation, and it acquires properties of a deleterious character that impart to the beverage with which such water is used an unpleasant flavour, which may be readily detected by any one who has given attention to the subject. The indifferent quality of the tea and coffee one meets with in most English houses may be referred to the fact that servants have an inveterate habit of filling the tea-kettle from the boiler, simply because it is "handy," instead of going a few paces to the cold water tap, which French servants would do, for they never think anything a trouble in order to secure the excellence of whatever is prepared by French hands. Perhaps there is no subject upon which English servants and persons of that class are so ignorant as on that of *water*, its properties and uses, and the various conditions which render it beneficial or unwholesome in the household.—*John Bull.*

Sir John Rose Cormack, M.D.—Intimation has been received by Dr. Cormack that it is the pleasure of her Majesty to confer upon him the honour of knighthood. This acknowledgment of Dr. Cormack's services to English subjects during the two sieges of Paris is supplementary to the decoration of the Legion of Honour which he has already received from the French Government in recognition of the skill and devotion he displayed in various battle-fields, and as surgeon of the famous *Ambulance Anglaise*, which was instituted by Sir Richard Wallace, and entirely supported at his expense. The public will see in this mark of her Majesty's favour a well-earned reward of Dr. Cormack's devotion to duty during a most trying and dangerous time; while the medical profession will feel that it is also a tribute paid to the wonderful success which accompanied his hospital treatment. To Sir Richard Wallace it must be especially gratifying that the labours of his lieutenant have merited her Majesty's approval. Rarely have the honours of a baronetcy and of knighthood been more worthily won than by Richard Wallace and John Rose Cormack.—*Scotsman.*

At a numerously attended meeting of the St. Olave's District Board of Health, Southwark, held on Tuesday last, an increase of £50 a year in the salary of Dr. J. Northcote Vinen, the medical officer of health was unanimously voted, in appreciation of the manner in which he has performed the duties of his office for the last sixteen years.

The Bow-street Division of the Metropolitan Police have presented Dr. Alfred Harvey with a silver salver, on the occasion of his retirement from the office of surgeon to the division after a long service. The salver bore the following inscription;—"E Division of Police of the Metropolis, Bow-street.—Only a small token of the esteem of our officers and men towards their kind friend, Dr. Alfred Harvey, who never spared himself to help and soothe any of them, often at times when a cheering word was so welcome. Our divisional surgeon is leaving us, and the loss is ours. May he be happy wherever he goes. In memoriam.—James J. Thompson, Superintendent. London, Christmas, 1871."

On the 11th inst., the students of the Charing-cross Hospital presented Mr. Barwell with a handsome claret-jug composed of glass and silver, richly ornamented and engraved. It was accompanied by the following letter:—"The students of the Charing-cross Hospital beg to present their congratulations to Mr. and Mrs. Barwell, and would feel gratified by their acceptance of the accompanying jug as a slight token of the respect and esteem in which Mr. Barwell is held by them." Mr. Barwell acknowledged the present in the following terms:—"Gentlemen,—The kind congratulations and the charming present which you have offered to us are very welcome to us both. Allow me for myself to say that I esteem this token of your regard most highly. As a constant memorial that such has been accorded me, I intend to have your gift engraved and to place it with your letter under glass, dedicating its use only to special seasons of rejoicing.—With the best hopes and wishes for your future welfare, I remain yours very truly. Richard Barwell."

In the metropolis last week 1,632 deaths were registered, being 261 below the average. To diseases of the respiratory organs, including phthisis, 582 deaths were referred, or 55 less than the corrected average weekly number in the corresponding week of the last ten years.

◆

NOTICES TO CORRESPONDENTS.

NOTICE TO SUBSCRIBERS.

The Publisher will esteem it a favour if subscribers will kindly make their payments—£1 2s. 6d.—for the past year 1871, in cheque or Post Office order, as stamps are so frequently lost through the post.

ADVANCE SUBSCRIPTIONS FOR 1872.

Gentlemen who desire to avail themselves of the reduction in price by payment in advance, must do so before the end of the current month.

Dr. Ready, Liverpool.—On the 12th inst.

We are reluctantly compelled to postpone several important contributions already in type; amongst them the continuation of Mr. Critchett's paper "On Cataract," and the conclusion of the article "On Disease of the Throat," by Dr. Prosser James.

Dr. McNab.—The copies were marked and posted to the addresses given.

Dr. Carey, Taunton.—Many thanks.

Dr. Abbott, Brigg.—On the 1st January.

Medical Society of London.—Erratum.—In our Report of the paper "On Preventive Medicine," read at the above Society by Dr. Ogle, of Derby, the words *healed easily* in the following sentence:—"Phthisis is one condition tending to disease, might be *healed easily*, and much harm prevented," should read thus:—might be *treated early*, &c.

"GOING ROUND."

To the Editor of the "Medical Press and Circular."

Sir,—To gratify the curiosity of my anonymous, but *would-be* jocose critic, "A Constant Reader," in the supplemental portion of your last number, permit me in great haste to inform him that I am not "Jumping Jim Crow," but

Ever truly yours,
Francis Edward Clarke, M.B.

Oughterard, Galway, Jan. 20th, 1872.

ELIGIBILITY OF SUPERANNUATED MEDICAL OFFICERS TO THE OFFICE OF GUARDIAN.

A Correspondent (J. B.) asks us: I am an ex-Medical Officer of a workhouse, and in receipt of the usual superannuation two thirds of my former salary. Am I eligible to be elected guardian or one of the guardians of said workhouse?

The Act of Parliament specifically provdes that any person receiving salary or emolument payable from the poors-rate is ineligible for the office of Poor-law Guardian of the union from which the payments are made.—Ed.

A FEW PRACTICAL REMARKS ON THE TREATMENT OF CATARACT.

By George Critchett, F.R.C.S.,

Senior-Surgeon to the Royal London Ophthalmic Hospital, Moorfields.

(*Continued from Page* 17).

There are two other methods of eliminating a cataract from the eye; the one by absorption or discission, as it is sometimes called, and the other by extraction. As the operation by absorption is only applicable to cataracts that are more or less soft, and as that operation did not come in as a substitute for couching or depression, it will be more convenient to defer the consideration of it and the cases to which it is specially applicable, and to proceed with the operation of extraction, an operation which, in some form or other, must always play the chief part in the surgical treatment of hard or senile cataract. It was, no doubt, in consequence of the many serious objections to the ancient operation of couching, to the large average of failures, and to the protracted and painful deep-seated inflammation that sometimes followed this operation, that attempts were madé at what must have appeared a far bolder and more difficult operation, viz., the removal of the cataract from the eye or extraction, as it is usually called, though this term does not quite correctly express the process—expulsion is more like what actually takes place. In order that we may clearly understand, and estimate the various modifications that have been recently introduced in the operation of extraction, we must briefly describe the original flap operation and endeavour to estimate its merits, its defects, and its dangers. I do not propose to enter into any historical details as to the steps by which the operation was gradually brought to its highest development, as it would not advance the practical questions upon which we are now engaged.

It is above a century since the first attempts were made by Wenzel, and they were evidently somewhat rude and unsatisfactory, since we find that he made a small incision in the cornea with a knife, and enlarged it with scissors. It is chiefly to Beer, and subsequently to Jager, that we owe the complete working out and the brilliant manipulation of the flap operation, "l'extraction à lambeau," as it is termed on the Continent. The former of these eminent and dexterous operators is reported to have confessed that he had put out a hat-full of eyes before he acquired sufficient dexterity to operate with certainty, and if we bear in mind that he had, in a great measure, to work out the details for himself, and had not the advantage of learning from others, and if we take into consideration the great and internal difficulties of the operation itself as he performed it, we shall come to the conclusion that the statement is not very far from the truth. The operation for cataract by the old method of extraction has been so often, and so well described in various works upon "Ophthalmology," that it would be tedious and unnecessary for me to enter minutely into the details involved in its performance. I must, however, in order to carry out the objects of this paper, dwell briefly upon the essential points connected with the operation, so as to contrast it with modern innovations.

In performing the orthodox operation for the extraction of cataract, the object aimed at is to make an incision of the cornea of a semi-circular form, either upwards or downwards, that shall lie just within the margin of the cornea, and shall represent the diameter of a circle rather less than the cornea itself. In order to accomplish this, a knife of a triangular form, known as Beer's knife, is introduced at the outer margin of the cornea carried across the anterior chamber, made to emerge at the opposite point of the cornea, and still carried on until it cuts its way out. If this be done with precision, and if the aqueous tumour be retained during the entire transit of the knife, the result is, that a semi-circular flap is formed, including either the upper or the lower half of the cornea. This, in fact, is the object to be accomplished, and if it fall short of this the fault is in the operator, and not in the plan of the operation. The hand has failed to carry out that which the mind intended. The next stage of the operation is to open or lacerate the capsule. The third and last stage is by making gentle pressure upon the eye at a point corresponding to the border of the lens, gradually to expel it through the corneal opening; the pupil, which has expanded to allow the cataract to escape through it, resumes its normal shape and size; the edges of the flap accurately adapt themselves, and the eye puts on its previous aspect, minus the aqueous tumour and the cataract. If the incision in the cornea heal, the aqueous is re-secreted, and the pupil remains central, the result both as regards the appearance of the eye, and the restoration of vision is as nearly perfect as can well be imagined.

It is difficult from any mere description, or even after witnessing a flap extraction skilfully performed, to realise all the difficulties involved. Let us suppose a case in which both eyes are to be operated on. The upper lid must be raised so as to fully expose the eye and yet not so as to make pressure on the globe. The triangular knife has then to be made to penetrate the cornea, exactly at the right point, to pass across the chamber with such accuracy as not to allow the thin aqueous fluid to escape by the side of the blade, to emerge at exactly the corresponding point of the cornea, its course must still be continued on until only a line of the corneal tissue be left undivided, and this progress of the knife must be so directed as to form a semicircular flap near the corneal margin, the last remnant of cornea must be divided so gradually and carefully by retracing the knife that the ultimate completion of the section is scarcely felt by the eye. Nor does the next step of the operation make much less demand upon the celerity and dexterity of the operator. The curette must be passed into the chamber and over the surface of the iris without entangling or even touching it, until it reaches the pupil, where the point must be so manipulated as to lacerate the capsule without disturbing or displacing the hard cataract contained within it. Having done its work, it must emerge again without touching the iris. Lastly, very gentle pressure must be made exactly at the right spot so as gradually to expel the cataract without a rupture of the hyaloid membrane or an escape of the vitreous humour, leaving the parts apparently very nearly in the same condition as before. If we suppose this operation to be performed upon a somewhat irritable person with sensitive and rather deeply set eyes, if both eyes be done, requiring that the operator be ambidexter, and that he display the same dexterity with the left hand as the right, if in addition to this his nerves be tried by the close scrutiny of several critical eyes, and perhaps still more by the weight of heavy responsibility and the reflection that the sight of a fellow creature is at that moment hanging upon the accuracy and steadiness of his hand; I do not hesitate to say as the result of my own rather large experience, that there is no operation in the whole range of surgery that requiries such a rare combination of mental and physical qualifications or that taxes so largely the resources of the operator, or that demands such a long course of mental and manual discipline, so that the eye and the hand may learn to execute with certainty the dictates of a prompt, experienced, and tutored mind, prepared at any moment to alter and modify the tactics as unforeseen casualties arise. It is not to be wondered at if we find that the public and the Profession have held in special repute the few who have attained the highest skill in the performance of this operation. I can well remember *the admiration and the envy with which I watched a skilful operator* in the dawn of my ophthalmic studies, take case after case with an equally sure result, This was the operation that has stood at the very portals of a high ophthalmic reputation. In the hands of the best operators the results were highly satisfactory, and it has been until a comparatively recent period considered the orthodox and recognised method, and even now it is so ranked by many high authorities. It is not to be wondered at that those who after careful study have acquired an exceptional amount of skill in performing the flap extraction and whose reputation as operators has reached to the highest pinnacle, should look upon any invasion upon the old established and orthodox process as little short of sacrilege, and should only yield inch by inch to the force of argument and the stern logic of facts; and I think it must be admitted that no small amount of credit is due to those who have at length so far yielded as to give up the operation they have so long and so skilfully performed, and commenced as it were *de novo* upon an entirely new method. Let us now take this operation into court and endeavour in an impartial and judicial spirit to consider both its advantages and its elements either of partial or of complete failure. It may at once be admitted that the flap extraction was a great improvement in every way upon the operation that was previously performed, viz.,—depression or couching. It is a method of operating that allows the cataract to escape from the eye very easily, without force or bruising. The only part that is stretched is the pupil, and when union of the corneal wound has taken place with accuracy the form of the eye is well preserved, so that the optical conditions for vision are well restored, as well in fact as it is possible to conceive. The pupil is small, central and clear, and the curvature of the cornea normal, and one operation usually suffices. A slight secondary needle operation is sometimes needed but this is exceptional. The operation occupies a very short time; the pain is slight and it is only during the first stage that even this small degree of pain is felt. Such are the chief and more obvious merits of this operation. It presented so many apparent and very manifest advantages, and gave what was once considered to be such a good average of success, that it may be said to have occupied undisputed possession of the field, and to have been so firmly established in public and in professional esteem that anything like a radical change of procedure seemed highly improbable, and any proposal to that effect would, a few years ago, have been received with surprise, and with considerable opposition. It will be seen that the recent modifications have been brought about very gradually and have only at length obtained a footing on account of the inherent defects of the flap operation which were felt more or less by every practical man, but which were scarcely hinted at until a plan in which these defects were less obvious had been devised. Even to this day there are many eminent and skiful operators who still prefer the flap operation, and who prophecy that ere long it will once more reign supreme. It will now I think be useful to inquire what are the weak points and the sources of failure more or less complete of the flap extraction. First and foremost amongst the objections to the operation I think we may fairly place the difficulty of performance. I have already alluded to it in describing the method of doing it, and those who have followed that description, who have watched the performance of it, or who have done it themselves, will readily estimate the force of this objection. If we consider how many operations of this kind have to be performed each year in different parts of the world, how oculists are increasing in number, and springing up in every town where civilisation is known, and how limited must be the means of acquiring sufficient dexterity to perform with any degree of certainty and success, this skill-demanding operation, its very difficulties become a serious objection to its adoption amongst those who are ambitious to represent and to practise modern ophthalmology; so keenly has this difficulty been felt that various methods have been suggested for fixing the eye in flap extraction either by the operator himself or by an assistant; but this again has some serious disadvantages: it augments pain, induces spasm; either deprives the operator of a hand that he wants for controlling the lid, or introduces an assistant whose co-operation at the critical moment cannot always be depended upon. If, therefore, it is capable of demonstration as I believe in a subsequent part of this paper it will be found to be, that the modifications introduced in the operation are more easy of performance, can be acquired more quickly and can be executed with greater certainty by those who possess the average amount of dexterity: then the difficulties of the flap extraction constitute a legitimate ground of objection and are amongst its weak points. The next to which I would allude is, that it leaves the contents of the eye in a very defenceless state. If at the moment that the section is completed, the muscles of the eye-ball or of the eye-lid or both are thrown into a state of spasm owing to the undue sensitiveness or irritability or nervousness of the patient; conditions that not infrequently exist and are beyond the control both of the patient and the operator; or if the latter inadvertently makes undue pressure on the globe or completes his section too rapidly and suddenly, the lens may immediately follow, together with more or less vitreous humour, an accident which always impairs, to a certain extent, the optical conditions of the eye and its longevity, and increases the risks and the duration of its recovery; and when the loss of vitreous is considerable, may eventuate in a complete failure. It is an accident that may occur to the most skilful operator, and is not an infrequent mishap amongst those who have not attained a higher standard of manual skill. The next objection is the same in kind. The absence of support and security to the contents of the eye caused by the corneal flap, is felt during the stage of healing; the flap merely falls into its place, and keeps in apposition by its gravity. The consequence is, that any undue effort on the part of the patient, as in coughing, sneezing, vomiting, or straining of any kind, or any spasm of the muscles during sleep, or in some troubled dream, or in the act of waking, or any slight blow—any one of these various causes is liable to produce a separation, more or less complete, of the cornea flap, and a protrusion more or less extensive, of the iris between the flaps, giving rise to that well-known and much dreaded and not infrequent sequel of flap extraction: prolapse of the iris. When this occurs the recovery of the eye is seriously retarded and sometimes prevented; the eye is placed under circumstances of great difficulty for repairing the wound that has been made, and when at length, after much suffering, and much trial of patience both to the operator and the patient, repair is effected, it is found that the curvature of the cornea has been considerably altered, that the pupil has been displaced in the most disadvantageous direction, and that only a very partial recovery of sight has resulted; whilst a certain degree of delicacy and unhealthiness of the textures frequently hangs on for months, preventing any resumption of active utility. Another objection to the operation is the large proportion of the cornea that is involved in the wound, thereby increasing the difficulty of attaining union by the first intention, threatening the transparency of the corneal flap, and favouring purulent infiltration; moreover, it is in this form of operation that the more formidable sequelæ most frequently occur, viz.,—suppuration of the globe and internal hæmorrhage. Both these unfortunate results are attended with severe pain and constitutional irritation, which, when superadded to the cruel disappointment inevitably resulting from the entire loss of the anticipated and anxiously hoped for sight, and at a period of life often when the lamp is somewhat flickering, this accumulation of misfortunes gives rather a serious and formidable aspect to the case, and has brought the operation into rather bad odour with the public, causing many a blind sufferer to look forward to the ordeal with dread, and probably has deterred many from encountering the risk; preferring "to bear the ills they have than fly to others that they know not of." There is yet one other aspect in which this operation may be viewed in reference to concomitant inconvenience and disadvantages. The success of the flap operation so much depends upon a perfectly quiescent and tranquil state of the eye, that it has been found necessary to enjoin a very strict discipline, to urge the patient to abstain from any sudden or violent movement; and even from laughing, talking, mastication of hard substances, &c. This enforced quietude becomes exceedingly irksome to many aged people, and it is the impossibility of inducing some patients to conform to these rules that has led to failure.

In this class of case it may be further remarked, where irritability, timidity, or extreme sensitiveness to pain are strongly marked, it is obvious that the use of anæsthetics is indicated, but in the flap extraction this is a dangerous procedure, in consequence of the liability to vomiting. The severe straining may cause, and has, caused the contents of the eye to be forcibly expelled, to the utter destruction of the organ.

It is true that this objection does not exist in all cases. Some elderly people of a quiet, tranquil temperament, find no difficulty in maintaining the requisite degree of repose, but on the other hand we meet with not a few on whose deeply wrinkled brow Nature has written in unmistakeable hieroglyphics an irritable temperament, and a proneness to powerful and spasmodic action of the facial muscles. In such temperaments the chances of success are much diminished, and the effects of failure very keenly felt. The very conditions that promote the occurrence of prolapse, and other casualties, aggravate the subsequent sufferings of those in whom they occur.

Such are amongst the principal objections to the flap operation, and it must be admitted that they constitute a very formidable indictment. It is true that a few dexterous operators have felt proud of the certainty with which they could triumph over the great difficulties inherent in the flap operation, and they have been able to point with legitimate pride to a good average of success, and to some cases that seemed to leave nothing to be desired. Yet even the best, if they deal quite honestly with themselves, will have to record cases that, in spite of all their care, and all their skill, have given them such an amount of anxiety as to neutralise and more than neutralise the satisfaction they derived from their successful cases. It is not surprising, then, that several of the leading ophthalmologists were somewhat eager to assist in carrying out any new train of thought that might lead to a method of operating, whereby prolapse of the iris is impossible, spasm of muscles and movement of patient unimportant, apposition of corneal wound inevitable, healing rapid, chloroform safe, and suppuration of globe extremely rare as compared with flap extraction. It is hardly too much to say that these advantages are obtained by the modified linear extraction, which it is the chief object of this paper to explain, describe, and illustrate.

(*To be continued.*)

◆

TWELVE CASES OF "BENT KNEE"-JOINTS (a)

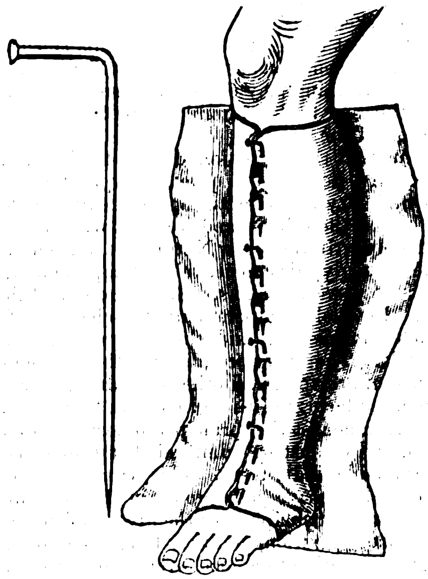
TREATED IN THE CITY OF DUBLIN HOSPITAL.

By Henry Gray Croly, F.R.C.S.I.

Senior Demonstrator of Anatomy in Royal College of Surgeons in Ireland.

Bent knee-joint (as has been truly observed by a very distinguished surgical writer) is one of the most distressing deformities to which the human frame is liable. If it be severe the leg is bent at nearly or perhaps at quite a right angle with the thigh. It is fixed in this position. The patient cannot put the sole of the foot or even the points of the toes to the ground; hence the limb becomes useless for the purpose of progression, and from want of exercise atrophies. But a badly bent knee is worse than useless—it is a positive incumbrance, for as the foot cannot be brought fairly to the ground the limb projects behind in a most awkward manner, swaying as the body moves round, constantly in the way, and liable to injury. The nutrition of the limb thus affected, becomes impaired from want of exercise, the foot is habitually cold, the circulation in it is languid, and the toes become liable to chilblains and troublesome ulceration. In the less severe forms of bent knee the inconvenience, though not so great as that just described, is very considerable, for as the patient can never bring the heel or sole to the ground he rests insecurely on the tips of his toes, and walks but insecurely with the aid of a crutch or stick.

(a) Read before the Surgical Society of Ireland.



Case I.—J. F., a lad, æt. 16, was admitted into the City of Dublin Hospital, under my care, in October, 1864, suffering from bent knee-joint.

History.—Five years previously an abscess formed in the lower and outer third of the left thigh, and was opened by a surgeon. No cause could be assigned for the abscess, and the patient enjoyed good health up to that time; a year subsequently he fell upon his left knee, inflammation of the joint ensued, and the knee became gradually bent. Obliged to use a crutch.

Condition of joint on patient's admission into the hospital.—The internal condyle of the femur projects considerably inwards and forwards; the tibia is partially luxated backwards and outwards; the back of the condyles of the femur rests on the anterior edge of the head of the tibia; the patella is displaced outwards; the hamstring tendons are tense; the muscles of the thigh and leg are wasted. The ends of the toes touch the ground; the heel is raised; the knee-joint can be flexed, but cannot be extended; the patient uses a stick, on which he leans when walking; his general health is good.

Treatment.—The limb was placed upon a well-padded McIntyre's splint, and fixed by a roller bandage. The screw of the splint was turned gradually to make extension. The treatment was steadily persevered in for some days, and then I performed tenotomy of the ham-string tendons in the following manner:—The splint having been removed, and the patient placed prone, the limb was firmly held by an assistant, the tendon of the semi-tendinosus muscle, which was most prominent, was first divided, by passing the tenotome flatwise beneath the integument and turning its edge against the tendon. The tendon of the semi-membranosus then became prominent, and was also divided through the same opening, and lastly the biceps tendon was cut, due care being taken to avoid injuring the peroneal nerve by keeping the edge of the knife against the inner edge of the tendon. A compress having been applied, the limb was replaced on the splint, but no further attempt at extension was made *until the wound healed.* The patient suffered but little pain, and when all irritation had subsided, extension was made cautiously and gradually by an occasional turn of the screw, and in about twelve weeks the limb was almost as straight as the sound one. The splint was removed, a starched bandage applied, and pasteboard splint. The patient was supported by nutritious food, and a liberal allowance of porter, with cod-liver oil and syrup of iron. He was discharged from hospital, and is now able to walk without any artificial support. He works at a trade, and has almost as good use of the limb as of the sound one.

Case II.—J. Q., a boy, æt. 16, was admitted into hospital for contraction of the right knee and inability to walk except by the aid of a crutch.

History.—He fell when ten years old and struck the patella. He suffered much pain from the injury. Inflammation and abscesses around the joint resulted. The knee became gradually bent, until at length he could scarcely touch the ground with the ends of his toes. He was received into a hospital in the city, but did not remain in consequence, as he said, of amputation being proposed to him.

State of the joint and limb on admission of patient into the City of Dublin Hospital.—Right leg flexed, condyles of femur projecting forwards and inwards. The toes pointed, and raised two inches from the ground, the heel six inches, the ham-string tendons prominent but not tense, the joint moveable. Flexion can be performed, but not extension. Two cicatrices are visible above the external condyle of the femur, the result of abscesses consequent on the injury. The boy is pale and delicate-looking. Similar treatment as in Case I was adopted. In two months the patient was discharged from hospital, the limb being straight. This young man is now engaged as a teacher in a school, and walks several miles daily, and uses neither crutch nor stick. The joint is *not* stiff.

Case III.—N. W., a girl æt. 5, was admitted into the child's ward of the City of Dublin Hospital, suffering from strumous abscesses around the right knee-joint, with contraction.

History.—Her mother states that the child was in good health until a month previously, when she complained of pain in the knee-joint. She limped, and kept her leg in the flexed position. The symptoms increased in severity, and she passed sleepless nights. Abscesses formed subsequently around the joint.

Appearance of child and condition of joint on admission into hospital.—The patient presented all the symptoms of hectic fever. The left knee-joint was enlarged, and the leg was flexed upon the thigh. The ham-string tendons were tense. The little sufferer screamed when any attempt was made to move the limb for the purpose of examining the joint.

Treatment.—The child having been placed fully under the influence of chloroform, the limb was fixed upon a gutta percha splint, which was moulded so as to support the joint. Liberal diet, with wine and quinine was prescribed. When all inflammatory action ceased I performed tenotomy. A splint was applied, and in one month the child was discharged from hospital, the joint being supported with a starched bandage and pasteboard splint. The child is able to walk, and to place her foot flatly on the ground. The joint is *not* stiff.

Case IV.—E. McM., æt. 18, was admitted into the City of Dublin Hospital in 1868, with contraction of the left knee-joint.

History.—Five years previously an abscess [illegible] the internal margin of the head of the tibia, and shortly afterwards another appeared on the lower and internal third of the thigh. The joint became swollen and painful, and contracted gradually.

Appearance of patient and limb on admission into hospital.—Boy looks delicate; walks on his toes; uses a stick; can bend his leg, but cannot extend it; condyles of the femur project forwards and inwards, tibia backwards; foot elongated; muscles of calf atrophied; ham-string tendons very tense. Tenotomy was performed; the leg *gradually* extended; limb put up in starch apparatus; boy now walks well, but the joint remains weak.

Case V.—John S., æt. 14, admitted into hospital Nov. 28th, with contraction of right knee-joint.

History.—He fell seven years previously on his knee. Inflammation of the joint set in. The leg gradually contracted. He walked on crutches for several years. His toes touched the ground. His heel was raised. The tibia was displaced backwards into the popliteal space. Leg rotated outwards. As there was considerable pain over the head of the tibia, and the boy's health was delicate, I placed his leg on a splint, applied blisters, and prescribed tonics, and when all inflammatory action ceased I performed tenotomy and gradual extension. Starched bandages, with paste board support, were applied from time to time, and in *a year* the leg became strong and useful.

This boy's parents seemed much disappointed at first, as they expected an improvement much sooner than could be attained. The boy is now able to walk well, and works at a trade. He promised to attend here to-night to be examined by any of the members.

Case VI.—A. B., æt. 14, residing close to the City, was admitted in winter, 1869, with bent knee. I met him walking on a crutch, and on examination found the joint contracted. He said he was seven years on a crutch. Tenotomy and gradual extension were performed, and the boy left hospital with his heel on the ground.

Case VII.—Henry Egan, æt. 27, was admitted into the City of Dublin Hospital, on the 10th October, 1870, with contracted knee-joint. States that when about four years old he fell down a flight of steps and injured his knee, which gradually swelled up to a great size, but did not prevent him walking as usual until the lapse of some months, when it became what he called "a white swelling," and it then compelled him to keep to his bed. He continued in bed for about six months, and on his again getting up he found his knee contracted, and could not put his foot to the ground, he then had recourse to a crutch, with which he was able to get about pretty well. He continued in this state for about four years, when his father put a kind of iron splint on the back of his leg, which after some time enabled him to touch the ground with his toes, and to walk with the help of a stick instead of the crutch. He then threw aside the splint, and was able to lean on his toes. About this time a small sinus formed on the inside of the joint, and this usually broke out in spring and healed up again after a short time, never discharging much matter; about four years ago, it healed up, after which the knee was no longer painful or tender, and he could flex it to a right angle, but from the time of injury could never *extend* it. He says that it continued in this state until his admission.

Case VIII.—J. H., æt. 11, was admitted into the City of Dublin Hospital, on the 21st of December last, suffering from contraction of the left knee-joint.

History.—Six years previously he fell on his knee, and received a slight wound. The joint inflamed; the boy became lame; blisters were applied; the leg bent gradually.

Appearance of limb on admission of patient into Hospital.—Joint very much enlarged; tibia displaced backwards; boy walks with the aid of a crutch, and his *toes* are *ten* inches from the ground; ham-string tendons very tense. Tenotomy performed; gradual extension, first by means of screw splint, and then by weight and pulley. This boy complained of severe pain over the head of the tibia, and got considerable relief from occasional blistering. *Joint not yet strong.*

Case IX.—James Leach, æt. 9. Contraction of right knee, result of a fall and subsequent inflammation; lower end of femur curved very much; tibia displaced backwards; limb *very short.*

Treatment.—Tenotomy; extension gradually forward by weights and pulley. Chloroform administered and leg *forcibly* extended; loud snap heard when old adhesions were giving way; limb placed upon a splint.

Case X.—E. A., female, æt. 21, residing in County Wexford, was admitted into hospital, in 1871, with contraction of right knee. She received an injury many years previously, and had inflammation in the joint. The leg was bent and finally very stiff; she could not make any attempt at straightening or bending; ham-strings very tense; femur projecting forwards and inwards.

Treatment.—Tenotomy; weight and pulley; for three weeks splint, then chloroform was administered, and joint forcibly extended; leg straight.

Case XI.—Margaret Roe, æt. 7, residing at Woodside, near Dundrum, was admitted into the City of Dublin Hospital, October 2nd, 1871, with contraction of the left knee.

History.—When five years old, she fell on the head of a shovel and hurt the knee cap; the joint swelled; her brother brought her to a bone setter, who pulled the leg; the leg gradually contracted. She was then admitted into a hospital in the City, and had blisters applied. The child was not kept in bed. A splint was subsequently applied in another Dublin hospital. Appearance of limb on admission into the City of Dublin Hospital. Left knee contracted; tibia displaced backwards; toes pointed; heel raised; patella displaced outwards; no pain in the joint or other symptom of inflammatory action. I performed tenotomy, and then chloroformed the child and forcibly extended the leg to the straight position. A suitable splint, well padded, was next applied and retained by roller bandage. Child gone home; leg quite straight.

Case XII.—C. H. J., a fine boy, æt. 10, fell when six years old on his right knee; the joint inflamed; leeches, blisters, and splints applied; symptoms relieved; boy allowed to walk about too soon; knee became bent. I saw him one year since. Boy's heel touched the ground, but there was some displacement of the femur forwards. I recommended sea-bathing, tonics, and rest. Joint improved. Six months ago the boy got a kick on the knee, when fresh inflammation set in; the leg became contracted; the tibia displaced backwards; ham-string tendons very tense. Boy admitted into City of Dublin Hospital October last. Leg placed upon a splint, blisters applied to joint over head of tibia.

Nov. 7.—Tenotomy of ham-string tendons performed; weight and pulleys are now applied, and the limb is now quite straight.

Observations.—When Case I. came under my care, I did not consider it possible that so much could be accomplished by tenotomy and gradual extension; in fact, I looked upon the treatment as preparatory to more severe operative interference. Finding the case improving, I persevered in the treatment, and the result was most satisfactory.

In Case II. the deformity was greater; the boy was seven years using a crutch, and it was with no small difficulty that I persuaded him to come into the hospital, as he believed nothing could be done to strengthen his leg. He is here to speak for himself and show his limb.

In Case III. there was active inflammation in the joint, and all the symptoms of hectic fever; and at one time I considered it more than probable that amputation of the thigh should have been performed, to save the child's life. This little girl is also here to night.

Cases IV. V. VI. and VII. nothing peculiar.

Case VIII. was an example of contracted knee of the worst kind; the leg was bent almost to a right angle, and the backward displacement of the tibia was very marked. *Inflammatory action had not ceased* when the boy came under my observation, and the disease was characterised by severe pain, increased on pressure being applied over the upper part of the head of the tibia. This boy's toes were ten inches from the ground when he was admitted into hospital. He can now lay his foot *flatly* on the ground.

Case IX. There *were no symptoms of inflammation* in this case. The lower third of the femur was curved as in the rickets. There was more stiffness in the joint in this, than in preceding cases, and finding that tenotomy and gradual extension were not likely to be successful, I chloroformed this boy and *forcibly* extended the leg. The old adhesions gave way with a loud snap. Case did very well; no pain or inflammation followed.

Case X. was sent to me by a medical practitioner of high position, as one suitable, in his opinion, for resection, in consequence of the useless condition of the limb. It was almost anchylosed; tenotomy and weight and pulley did some good, but the fascia in the popliteal space remained very tense. I chloroformed this patient, and forcibly extended the lég. The old adhesions were broken through, and the leg straightened.

The fact of so many cases of bent knee occurring ought to impress forcibly upon the mind of every student and practitioner the necessity of placing the limb in cases of inflammation in the knee joint, upon a suitable apparatus during the treatment, and thus prevent the deformity, which is certain otherwise to follow.

Tenotomy of ham-string tendons is of much more recent date than in cases of club-foot. The operation can be safely performed with ordinary care; the semitendinosus at first seems most prominent, but when divided the semimembranosus becomes tense; in dividing the biceps tendon of course the peroneal nerve must be carefully avoided, by keeping the edge of the knife against the internal edge of the tendon. *A probe-pointed tenotome is very useful.* The knife should not be used in the *centre* of the popliteal space, though the tense fascia in that region tempts the operator to divide it. The anatomy of the space becomes much altered by the displacement, backwards, of the tibia, and the popliteal tendons consequently much nearer the surface. In each of my cases I performed tenotomy, and in the first eight cases extension *gradually* by means of the screw-splint, or weights and pulleys sufficed; yet in Cases 9, 10, and 11, forcible extension was absolutely requisite; and, in my opinion, quite safe. No attempt at *forcible extension* would be justifiable if *any inflammatory action still existed.* No inflammation followed any of my operations.

Causes of Anchylosis are as follows; viz,—

1.—*Extra articular.* Shortened muscles, ligaments, fasciæ, cutaneous textures and cicatrices; for example—adhesions after burns, Erysipelas, Abscesses, &c.

2.—*When inflammation* has extended into the joint.

3.—*Osseous, which is rare.*

The deformity may be of two kinds; viz.—contraction with mobility, and no displacement of the bones; or contraction with bony displacement.

Chronic contraction, which exists in most of my cases, may depend on—

Consolidation of the ligamentous structures in or around the joint, or permanent constriction of the muscles.

The crucial ligaments are shortened, and there is a threefold displacement; viz.—Femur forwards, tibia backwards, leg and foot outwards. The ligamentum patellæ and extensors are weakened, the ham-strings are *unopposed*, the biceps overcomes the others. To test the amount of angular deformity, place the patient in the prone position, and the angle which the leg forms with the thigh shows the amount of displacement.

Treatment.—1. Mechanical extension *alone.* 2. Tenotomy and *gradual* mechanical extension. 3. Forcible extension under chloroform, preceded or not by tenotomy.

M. Louvrier, so far as I can ascertain, was the first to recommend forcible extension in these cases, and the practice was sanctioned by Blandin and Velpeau.

Dieffenback recommended tenotomy in the first instance, and then forcible extension. Professor Ferguson calls them to task sharply for such practice, and prefers tenotomy and gradual extension in mild cases, and says in the present day, *resection* of the knee joint might in other cases of bent knee be deemed the wisest practice.

In angular contractions, Mr. Erichsen recommends a screw-splint, with gradual or forcible extension; the latter he prefers as the speediest as well as a perfectly safe and effectual method. It would seem as if the synovial membrane, in some of the cases, lost its susceptibility to inflame. If the threefold displacement, already alluded to, exists, the *ham*-string tendons *must be* divided.

In cases of *Osseous* Anchyloses Alex. Barton, of Philadelphia (in 1835) proposed an operation for angular deformity of the joint. The operation consists in excising a wedge-shaped piece of the shaft of the femur, not including the whole diameter, and then fracturing the undivided portion and strengthening the limb. Birch (of New York), modified Barton's operation, and recommended sawing out a wedge-shaped piece of the condyles of the femur, including the head of the tibia and patella.

Drilling the bone, and then fracturing, has been recommended by Brainard. Forcible subcutaneous separation of tibia and femur has also been recommended.

These severe and dangerous operations are not, in my opinion, justifiable.

UTERINE NEURALGIA AND ITS CHIEF COMPLICATIONS:

THEIR PATHOLOGY AND TREATMENT.

By John Chapman, M.D., M.R.C.P., M.R.C.S.,

Physician to the Farringdon Dispensary.

(*Continued from Page* 55.)

Treatment.—According to the general confession of the Profession uterine neuralgia and its complications form part of that large group of maladies the treatment of which has always been extremely unsatisfactory. Its chief aim, of course, has been to overcome the chief evil—pain, and secondarily, it has been directed to effect the removal of uterine congestion or inflammation, to facilitate the menstrual process, and to improve the general health. The pain is usually combated by narcotics, by nauseating remedies, by warm baths, and by the application of sedatives both to the hypogastric region and *per vaginam.* In those cases in which congestive or inflammatory symptoms are present local depletion is urgently recommended, and in some cases even general bleeding is also advised. Improvement of the general health is sought to be effected by tonics, exercise, or bracing climate, and an abundance of fresh air. The success achieved by these practices is, as a general rule, so deplorably slight that uterine neuralgia and its kindred maladies have long held a conspicuous place among the *opprobria* of medicine; and indeed, this can be no matter of surprise if the pathology of these affections as sketched above be true; for obviously the therapeutical desideratum is a power of lessening the energy of the nervous centres implicated, and none of the remedies enumerated above possess that power except when so used as seriously to impair the general health, and indeed to prove dangerous to life itself. That therapeutical desideratum is, however, according to my experience, completely fulfilled by the Spinal Ice-bag, *suitably* applied from 30 to 90 or even 120 minutes two or three times a day. I say "suitably applied" because its tolerance, its harmlessness, and its efficacy depend on the fulfilment of this condition. If the patient does not suffer from headache, and if her lungs are quite healthy, the Ice-bag may be advantageously applied along the spine from the middle of the cervical region down to the third or fourth vertebræ, *but not lower.* Headache, with cerebral hyperæmia as its proximate cause is, however, a frequent concomitant of uterine neuralgia, and in such cases cold ought not to be applied along the upper part of the spine, but should extend only along the six or eight lower dorsal, and the three or four upper lumbar, vertebræ. In these cases I generally use the upper two cells of a 20-inch Spinal Ice-bag applied along the part just described, the lowest cell remaining empty and either doubled behind the middle cell, or dependent over the sacrum. I adopt this plan in order securely to restrict the ice to that part of the spine intended to be acted upon; if ice were put in the two lower cells of the Spinal Ice-bag the upper one being left empty, and if after the two lower cells were applied along the lower part of the spine the patient were to lie down on the bag, the melting ice would flow back towards its mouth, and thus, contrary to my intention, the cold would come in contact with the upper part of the spine, and by lessening the energy of the collateral ganglia of the sympathetic would facilitate the dilatation of the arteries supplying blood to the brain, and this dilatation would increase the cerebral hyperæmia supposed to be already present, together with the headache dependent upon it. Whereas, if by means of the upper two cells of the bag the ice be restricted as described along the lower part of the spine the afflux of blood to the lower half of the body will be increased by vaso-motor agency, blood will therefore be derived from the brain, and the head-ache thus relieved by removal of its proximate cause, will quickly cease.

Pulmonary disorders of any kind when complicating the principal malady necessitate the exercise of especial caution in prescribing the use of the Spinal Ice-bag; in all cases thus complicated the medical attendant should scrupulously avoid its application between the scapulæ. In the treatment of these cases I use a bag which I expressly devised for the purpose of exerting a special influence on the pelvic organs, and which I call the 'Lumbar Ice-bag.' It is about ten inches long and consists of two cells. When the associated pulmonary disorder does not affect the lower lobes of the lungs both cells of this bag may generally be used in order to combat the uterine disease, and generally with an indirectly, but greatly beneficial influence on the pulmonary affection. The bottom of the lowest cell of the bag should be on a level with the 3rd or 4th lumbar vertebra—not lower; the bag will thus reach upwards to the lower angles of the scapulæ. If however bronchitis or other pulmonary disorder should extend to the lower lobes of the lungs, or if the bag applied as just directed should add to the already existing discomfort in the chest the ice should be used only in the upper cell of the bag, and that cell should be brought down so that the bottom of *it* may be on a level with the 3rd or 4th lumbar vertebra—the bottom cell being doubled behind the top one, or hanging empty below it. In this way not only may all injury of the lungs be avoided, but a remedial influence may be actually exerted upon them and often to a surprising degree, chiefly no doubt through the agency of derivation, partly however, I believe through the directly sedative influence of the ice on those spinal centres, from which trophic nerves convey nutritive energy to the pulmonary structures.

Having duly regarded in the manner just indicated the cerebral and pulmonary disorders often associated with the uterine disease in question, the physician will find that he may treat it successfully by the prolonged use of the Spinal Ice-bag. The longer each application of it is continued, provided always that the patient experiences no discomfort from its use the sooner will success be attained. But it must be constantly borne in mind that as a condition of success this treatment must at least be thoroughly comfortable if not positively pleasant; therefore the medical attendant may feel assured that if the application of the Spinal Ice-bag causes either pain or decided discomfort, it is either applied wrongly or applied too long at a time. In some cases it is inexpedient to apply it for more than 20 or 30 minutes, in others it may be borne until the ice is quite melted, on each occasion. But a correct diagnosis of all the pathological conditions of each case, a due consideration of the physiological influence of the ice on each part of the spine in relation to those conditions, and the exercise of sound judgment in determining the part of the spine to which the ice ought to be applied, as well as the length of each application, will enable every Medical man of average intelligence and professional culture to avail himself successfully of the therapeutical method in question. A large experience of it justifies me in affirming that when it becomes generally known and adopted, it will be recognised as fraught with great and especial blessings to a large proportion of womankind. By one and the same simple process uterine pain and its frequently associated disorders, difficult menstruation, nausea, vomiting, constipation and irregular action of the bowels, frequent urination, leucorrhœa, and coldness of the feet, are in the great majority of cases completely abolished; and very often cerebral and pulmonary affections, which sometimes originate directly from the same cause as the disorders just mentioned, and sometimes secondarily by their agency subside simultaneously and entirely under the influence of the same treatment.

◆

A CLINICAL REPORT OF THE ROTUNDO LYING-IN HOSPITAL, FOR THE YEAR, 1871. (*a*)

By George Johnston, M.D., Master of the Hospital.

Mr. President and Gentlemen,—In presenting these reports of the great institution, of which I have the privilege and honour of being Master, my object is not to advocate any particular theory or principle of my own, but fairly to test the question, whether large internal maternities are, or can be made, safe asylums for lying-in women.

During the past twelve months, the healthfulness of the hospital has been severely tested, inasmuch as—and, of course, you must be all well aware—epidemics of various kinds, and of a serious nature, such as typhus and typhoid fever, erysipelas, scarlatina, and latterly small-pox, have from time to time prevailed, to a considerable extent in various parts of the city and suburbs, while the hospital, although admitting patients, not only from localities where the diseases existed, but absolutely from among families, many of whom had died, or were suffering from the epidemic(*b*) and some even had the disease actually upon them when admitted, I continued healthy, as in no one instance did the malady extend beyond the individual so affected.

During the year terminating the 5th November, 1871,
There were 1,161 intern labour cases, beside which
181 cases were delivered at their own homes,
4,028 attendances at the dispensary, and
203 were under treatment in the chronic ward.

Making in all 5,573 cases relieved in the year.

Of the 1,161 intern labour cases (403 were primiparæ and 758 were pluriparæ) 963 were natural labour, *i.e.*, head presented, and the labour terminated within twenty-four hours; 19 lasted upwards of twenty-four hours, but did not require artificial aid; 24 were abortions; 56 were præternatural cases, 8 of which presented with the shoulder, elbow, or hand; 48 where the breech or lower extremity was the presenting part; 64 cases had to be delivered with the forceps; 6 instances where craniotomy had to be performed, and delivery effected in two with the crotchet, and in 4 with the cephalotribe. In 5 of these cases there was distinct evidence as to the death of the child before operation; in 1 it was doubtful.

In 39 cases the labour was complicated, viz., 16 being twins, 8 were cases of accidental hæmorrhage, 1 of placenta prævia, 5 *post-partum* hæmorrhage, in 9 cases the placenta was retained by morbid adhesions; there were 8 cases of prolapse of funis, and 1 rupture of uterus, 2 convulsions, 1 epilepsy; mania occurred in 12 instances; in 55 chloroform was administered.

There were 25 cases of peritonitis, 1 of puerperal fever, 1 of metritis, 5 of phlebitis, 4 of pyæmia, 4 of sloughing of vagina

---

(*a*) Abstract of a Paper read before the Dublin Obstetrical Society.

(*b*) In one instance four children died of scarlatina.

and perinæum, 1 of gangrene of the uterus, 5 of scarlatina, 1 of variola, 3 of erysipelas, 2 of typhoid and 1 of typhus fever; 36 cases of bronchitis, and 1 of pneumonia.

I think in justice to the question (as to the safety or otherwise of large maternities) it is but right and fair to lay before you the following list, showing the *condition* in which the several patients presented themselves *on admission:*

There were 5 cases of what I may call malpraxis. 7 cases where the child was born for some hours before admission, and therefore the mothers were exposed to all the dangers of hæmorrahage, inflammation, &c. 47 were in very delicate health, suffering from great debility; 8 cases of exhaustion from accidental hæmorrhage, 1 from unavoidable hæmorrhage, 36 from bronchitis, 2 from pleuritis, 3 from phthisis, 1 pneumonia, 2 from laryngitis, 1 tonsilitis, admitted from another hospital; 3 inflamed varicose veins, 1 erysipelas of head, 3 injuries received by beating, 1 influenza, 1 hæmoptysis with peritonitis, 1 jaundice, 1 epilepsy, 3 condylomata, 1 secondary eruption, 3 purulent vaginitis, 1 variola, 1 hysteric convulsions, with hæmorrhage (3 months), 1 typhus fever.

It will be observed that our mortality, amounting to 33, is considerably more than either of the former years, still, on examining more closely into the circumstances of the deaths, it will be clearly seen that these deaths would have taken place had they been confined in their own homes, or even in cottage hospitals or detached buildings.

The number of deaths as I have before stated, amounted to 33—viz., 1 was brought in in a state of great exhaustion from placenta prævia, 2 in a feverish state, sloughing of vagina followed; 2 cases of sloughing of vagina, peritonitis followed, both were innupta; 2 cases of sloughing of vagina with pyæmia, one was innupta, the other was in delicate health for three weeks previous; 8 cases of peritonitis, 4 of which were innupta, 3 were labouring under great distress of mind, and 1 had been in labour under care of a woman for two days before admission; 1 case of pyæmia, innupta, great distress of mind; 2 cases of phlebitis, one had inflamed varicose veins on admission, the other in very delicate health, attacked with mania on fourth day from bad news, when phlebitic inflammation followed; 1 case of typhoid fever, 1 of scarlatina, an innupta; 1 case of erysipelas, a delicate woman; 4 cases of bronchitis, 1 of which had pneumonia, in 2 peritonitis followed, 2 of these were innupta; 1 of phthisis, 1 with hæmoptysis and peritonitis on admission; 1 of pneumonia. There were 3 died suddenly, 1 of clot in the left ventricle, 1 of rupture of a varicocele in left spermatic vein, 1 of embolism, 1 having had bronchitis for three weeks, 1 of gangrene of the uterus, an innupta, and 1 of rupture of uterus, also innupta, had been under treatment for "dropsy" for some time before admission.

It will also be found, and I wish to draw your attention to the fact, that of the 33 deaths, 13 were cases of *seduction*, 5 were suffering under great distress and anxiety of mind, 5 from extreme delicacy of health, 2 were admitted with all the symptoms of fever, 1 with phlebitis on admission, 1 with phthisis, 2 with pneumonia, 5 with bronchitis, 1 with hæmoptysis and peritonitis, 1 had scarlatina latent, which developed itself on the third day.

So that we may safely say that in no one instance could the death, in any sense, be attributable to the patient having been confined or brought to the institution.

Again, in order to show in another point of view, and I think, more distinctly, that where deaths, particularly of a zymotic type, occurred, there was not contagion in any single instance. I beg leave to submit to your notice a table of the number of patients delivered in each ward, with the number of deaths, as they occurred, in the several months during the year.

I also submit to your observation a table setting forth the total number of zymotic cases, including puerperal fever, peritonitis, pyæmia, phlebitis, scarlatina, typhus and typhoid fever, erysipelas, and variola, which occurred in the hospital during the past twelve months. It is arranged in the order in which the several cases appeared, so that it will be seen that, although these sicknesses occasionally showed themselves, they were not the result of contagion or any epidemic influence in the hospital, but were simply owing to the circumstances in which each individual patient laboured either on admission or during her puerperal period.

On looking over the list it will be seen that 50 cases of zymotic disease, in one form or other, occurred.

Of these 50 cases, you will perceive that 23 were innuptæ, or nearly one-half.

And, again, in order still further to prove that, although diseases of a contagious nature may prevail outside, and yet the hospital be perfectly exempt from it, I refer you to another table, framed in accordance with that of the Registrar-General.

Thus showing that, although there may be an enormous amount of fatal disease occurring outside, the hospital proper may remain, comparatively speaking, free from it, and is a strong corroborative proof, if any further was wanting, that a large maternity can be a safe asylum for parturient women.

FORCEPS DELIVERIES.

There were 64 cases where delivery had to be effected by the forceps, 47 of which were primiparæ, and 17 pluriparæ, giving birth to 26 male children, 2 of which were dead born; one 8¾ lbs. weight, the mother having been 11 hours in the second stage owing to the head being in the second position; the other weighed 9 lbs. 6 oz., the mother had been in labour 2 days before admission; both mothers recovered. All the female children, 22, were born alive. Ten children died some time after delivery, viz., 7 boys and 3 girls; 6 died from exhaustion or compression, viz., 4 boys and 2 girls; 2 died of erysipelas of head; 1 of convulsions, a boy; and 1, a girl, was overlain. Fifty-five of the mothers recovered. Of the 9 deaths, 6 were primiparæ, 5 of which were innupta, 1 doubtful, and are thus accounted for.

VERSION.

There were 7 cases where we were obliged to perform version, 5 of which were owing to the upper extremity presenting; in one, a case of deformity, where we were eventually obliged to deliver by craniotomy, and one, a case of prolapse of funis, the waters had escaped eight hours previous to operation. Five of the children were born alive; of the two dead, one had to be delivered by craniotomy; in the other instance the liquor amnii had drained away four days prior to admission. All the mothers recovered.

PROLAPSE OF FUNIS.

There were 8 instances of prolapse of the funis: 1 a primiparæ, 7 pluriparæ. In 2, delivery was effected by version, both children alive; in 2 the funis was pulseless on admission, so labour was allowed to be terminated by the natural efforts; in 2 others the labour was so quick as not to require interference; in both the child was born alive, but one survived only ten minutes; one was delivered by the forceps, child lived only a few minutes; and in another the forceps were tried, but owing to contraction of the brim the head had to be lessened, funis having ceased to pulsate. All the mothers recovered.

PLACENTA PRÆVIA.

There was one case of unavoidable hæmorrhage, æt. 40, tenth pregnancy, admitted in the eighth month, in a state of great exhaustion, hæmorrhage having set in a week before. She was plugged, strength supported, and, as soon as the os would admit, the hand was introduced and version performed, and the child, d.p., extracted. Her strength was tried to be supported by beef-tea and brandy, both by mouth and enema, but she sank in eight hours after delivery.

ACCIDENTAL HÆMORRHAGE.

There were eight cases of accidental hæmorrhage, all being multiparæ, viz., one her third pregnancy, one her fourth, one her fifth, two in their sixth, two in their eighth, and one in her eleventh pregnancy, giving birth to six male children, two of which were alive; two females, both of which were alive. All the mothers recovered.

POST PARTUM HÆMORRHAGE

occurred in 5 instances, 4 in primiparæ, 1 in her second pregnancy, 1 in primipara died of gangrene of the uterus, all the others recovered. In three cases the ergot and cold water by injection were sufficient to arrest the hæmorrhage; in 2, had to employ the solution of perchloride of iron.

PLACENTA MORBIDLY ATTACKED.

There were nine cases where placenta was retained from morbid adhesion, 3 in primiparæ, and six in pluriparous patients; 8 recovered; 1, a primipara, died from a rupture of a varicocele in the left spermatic vein.

CONVULSIONS.

There were two cases of eclampsy, both primipara, one a case of twins; the first was attacked with convulsions when the os was nearly fully dilated, cold effusions, turpentine, assafœtida enema, sinapisms to calves of legs and back of neck, and the delivery was effected by the forceps of a boy living. She was afterwards put on bromide of potass., with belladonna, with good effect, although having an attack of mania on the fourth day, she eventually went out well. The second twin case, the convulsions did not occur till 7 hours after delivery. She was healed in the usual way with turpentine, assafœtida enema, sinapisms, cold effusion, and afterwards chloroform, with good effect. Her convalescence progressed slowly but favourably, and was discharged well. This woman had altogether 20 fits.

MANIA.

Mania occurred in 12 instances, 7 of which were primiparæ, and 5 pluriparæ; all were delivered by the natural efforts; 2 of the primiparæ had to be sent to the lunatic asylum; 6 were discharged sufficiently recovered; 2 their husbands removed, 1 on the eighth day, and 1 on the seventh day. There were 2 deaths, one an innupta; mania took place on the second day, followed by peritonitis, of which she died; one, a delicate, irritable woman, received some bad news on the fourth day, which brought on the attack; phlebitis ensued, of which she died.

The treatment generally adopted was, in the more severe cases, by solution of tartar emetic, and afterwards the hydrate of chloral; in those of a less severe character, we found the chloral or opium was quite sufficient.

In conclusion I would merely add, that feeling fully convinced of the inestimable value of statistics drawn from such sources as these have been, when their truthful accuracy can be really depended on, I have been induced to bring them forward, without any comment of my own, simply laying before you the facts in order to show the real sanitary condition of a large maternity, so that you may be able to form a just estimate as to the safety or otherwise of such an institution as the Rotundo Lying-in [illegible]

[illegible]PIPHYSARY FRACTURE. (a)

[illegible] subject of epiphysary fracture has always been of much interest to the Irish School of Surgery, and as the opportunities of examining these accidents after death are by no means numerous, I thought it would interest the society to lay before them a remarkable example of this injury occurring simultaneously to both thigh bones.

A boy, æt. 15, was admitted to Steevens' Hospital suffering from those terrible mutilations unfortunately too common in accidents from machinery. The right arm was torn off, leaving four inches of the humerus projecting, but as is so usual in such lacerations, there was no hæmorrhage. The right knee presented a compound fracture, four inches of the femur were protruded through a lacerated wound in the outer and back part of the popliteal space. The end of this fragment had the smooth formed surface characteristic of the epiphysary extremity. The popliteal artery could not be felt in the wound, but there was evidence that it had escaped injury, in the facts that no blood escaped from the wound, and the pulsations of both the anterior and posterior tibial arteries could be distinctly felt. At the left knee there was also a fracture above the joint, with the upper fragment projecting backwards and outwards, but the integument remained perfect, although tensely stretched over the bone. The collapse was extreme. Addressing ourselves to the treatment of these injuries seriatim, we first removed with the saw the projecting portion of the humerus, and brought the integuments as a flap over the wound. The right femur was easily reduced through the large wound in the popliteal space and the integument brought together and sealed with carbolic oil, leaving an outlet for discharges. But the greatest difficulty was experienced in reducing the fracture of the left side, and an amount of force had to be exercised, which was truly surprising, both limbs were secured with long splints, and stimulants freely given. He rallied for some time, but died of exhaustion in eleven days. The appearance of the bones is peculiar, as in both the fracture appears to have departed from the epiphysary line as it passed inwards as if the consolidation of this line commenced internally and extended outwards. I may mention that it was ascertained by examination that the artery had escaped injury.

Hospital Reports.

KING'S COLLEGE HOSPITAL.

Dislocation of the Hip.—Reduction without Chloroform.

(Under the care of PROFESSOR WOOD, F.R.S.)

THIS was a case of dislocation upwards on to the dorsum ilii, presenting all the characteristic symptoms, viz., absence of the hollow beneath the trochanter, the head distinctly felt in its new position, shortening of the limb and inversion, the toes resting on those of the opposite foot, &c. The accident occurred thus, a carpet was thrown out of a window and the man as he was passing by endeavoured to catch it, so as to prevent its falling on his head, and in doing so slipped down on his side.

The man objected to take chloroform. Mr. Wood first tried "manipulation," as the case had only happened two hours previously. Failing in this, traction was resorted to, the pulleys were then adjusted and after a good deal of patience and manœuvring the dislocation was reduced. No "snap" however was heard, and there appeared to be a little shortening; this however was apparent, not real, and owing probably to spasmodic contraction of the muscles, as by measurement it was found that the distance from the anterior, superior iliac spine to the great trochanter was equi-distant on both sides, and the distance from the same spine to the outer head of the tibia equidistant also. The knees and the ankles were tied together and the patient was carried to bed.

Professor Wood observed, that although manipulation had failed in this instance, it might be fairly attributed—1st. To the great muscular development of the man, and 2nd. to his declining to take chloroform; still, if they had noticed the several successive manœuvres he had employed, they (the pupils) would have noticed that they were precisely similar to the operation he had subsequently performed, *minus* the addition of the pulleys. That is to say, by first employing adduction, then flexion, abduction and rotation outwards, he had endeavoured to untwist or trick the ilia-femoral ligament and to hit off the opening in the capsular ligament as you do the opening between the subscapularis and long head of the triceps in dislocation of the humerus. This second part of the manœuvre is by no means easy and, like "chuck-farthing," you may have to repeat the experiment, that is employ all the manœuvres aforesaid before succeeding in returning the head of the bone. What really takes place when you do succeed, is that the pyriformis and gluteus minimus become relaxed and the head passes between these and then through the opening in the capsular ligament. In fact a surgeon will best show his ability who, when one plan fails trys another and so on, until the opening in the capsular ligament is discovered.

Again you must take care that before you commence using the pulleys to see that the axis of the displaced limb is in the line of extension.

Sir Astley Cooper says that if you *stand the patient up* the shortening is very apparent. Professor Wood has noticed that, from the difficulty experienced by patients with this dislocation to move the unaffected limb, he has never been able to stand his patient up, nor does he see any possible advantage by doing so. Finally, he noticed that many of the illustrations of hip dislocation in books represented the patient as lying on a bed while reduction was taking place, such drawings are apt to mislead, the proper place is on the ground and the patient lying on a mattrass.

◆

RICHMOND SURGICAL HOSPITAL.

Case of Incarcerated Femoral Hernia.—Operation.—Recovery.

(Under the care of Mr. Robert Adams)

Reported by Agmon B. Vesey, Senior Resident Pupil.

Anne Conway, æt. 28, servant, was admitted into No. 11 ward, Richmond Hospital, on Thursday, 10th November, 1870, under the care of Mr. Adams, suffering from a femoral hernia of the left side; states that twelve months ago, after being confined, a lump appeared in the left groin, which used to disappear when she lay down. She suffered no inconvenience from it. At the end of six months it had disappeared altogether up to Monday, 30th October, eleven days previously to her admission into the hospital.

The cause she attributed of the returning of the tumour in the left groin was an effort she had made to raise a weight. She distinctly felt something giving way in the left groin at the moment of her making the exertion; no tumour, however, appeared.

On Friday morning, 4th November, 1870, seven days previous to admission, she felt sick, but did not vomit, also felt giddy; took a dose of castor oil, and went to bed. She now felt a tumour in the same situation that it had been formerly. Was at first soft, and free from pain.

On Saturday, the 5th, the day after, the tumour became hard and painful, she states she was in so much pain she did not feel able to get out of bed, but her occupation compelled her to do so. Her bowels were moved three and four times daily up to the night before admission into hospital. It gave her great pain when at stool, accompanied with griping pains in the belly.

As the tumour was getting harder, she went to the Rotunda Lying-in Hospital, and was sent from there here. She applied, and was admitted on Thursday, 10th November, at eleven o'clock p.m.

Symptoms on Admission.—A tumour about the size of a hen's egg is found in the left groin, its long axis below and parallel to Poupart's ligament. It is very hard and resisting to the touch, very painful when the least pressure is made on it. No vomiting, no hiccough, no tympany of the abdomen. Pulse 90, feels thirsty. Bowels not moved since late last night. Put to bed, and cold lotion constantly kept to the tumour.

Nine o'clock, p.m.—I tried the taxis, but as the tumour was still very tense and very painful to the least touch, I did not persevere more than for a few minutes. No impulse given when she coughs, but it pains her very much, particularly at the inner side of the tumour.

Operation.—Friday, Nov. 11.—A consultation of the surgeons of the hospital was held shortly after her admission, and it was considered that nothing but an operation could succeed in this case, and the woman by four o'clock having been brought fully under the influence of chloroform, Mr. Adams commenced the operation by transfixing the skin and dividing the different thin layers of membrane which covered the fundus of the sac. This being fully bared, was found to be very hard, and so very tense that the most careful manipulation could not be effectual to point up between the finger and thumb any portion of the sac whatever. The woman being then fully under chloroform, it was thought advisable before going on further with the operation or opening the sac to try the taxis now on the denuded hernial tumour; this was pressed gently but steadily, and the hernia gradually was returned into the cavity of the abdomen. The sac, as already mentioned, was not opened, the hardened tissues which constituted the rising, through which the femoral hernia had protruded, but was not of course divided, as the hernia had been fully reduced. The simple incision, about two inches in length, which lay obliquely on the place the swelling had occupied, according to the line of Poupart's ligament, was united by three stitches, and cords on adhesive straps and compress applied, and the whole sustained by a spicæ bandage, the patient was brought to her ward.

Eight o'clock, p.m.—Pulse 84; passed fæces half an hour after having been removed to bed; no vomiting since the operation; seems cheerful; complains of bandages being rather tight; got a seidlitz powder.

Nov. 12.—Pulse 120; tongue dry; had a good night; slept at intervals; bowels not moved since; no rigor; has a slight tickling cough. Seen by Dr. Adams, who considers her going on well; ordered

Saline effervescing draughts every third hour,

Ice, and if bowels are not moved towards evening, to get an enema of

Mist rosæ cathact, ℥viij. (hosp. formula).

Nine o'clock, p.m.—No motion from the bowels since; gave her the enema; not inclined to sleep.

Haust anodynus.

Nov. 13.—Pulse 120; the enema has had the desired effect; slept well; tongue dry; no tenderness or tympany of the abdomen; ordered

Mist rosæ cathact, ℥viij;
st ℥ij tertiis horis

until the bowels are well moved; afterwards, to remove the stitches,

Ice and mist salina effervescents to be continued.

Eleven o'clock, a.m.—Her bowels have acted five times since this morning; seems much improved; pulse 110; tongue moist; removed the dressings and the sutures; some slight healthy discharge and tenderness around the edges of the incision.

Nov. 14.—Ordered a bread-and-water poultice to the part.

Dec. 12.—Since last report everything has gone on satisfactory; the wound was poulticed for a week; afterwards the edges of the incision were brought into apposition with strips of adhesive plaister.

She suffered occasionally from constipation of the bowels, which, however, always yielded to a dose of house medicine. At this date the wound is quite healed, and the patient walks about the ward. A compress and spicæ bandage continued.

Dec. 14.—Left hospital to-day.

Transactions of Societies.

MEDICAL SOCIETY OF LONDON.

MONDAY, JANUARY 15TH, 1872.

DR. ANDREW CLARK, President in the Chair.

OPERATION FOR TUMOUR OF THE TONGUE.

MR. WEEDON COOKE narrated the particulars of the case of a young lady, æt. 12, who had suffered from a tumour of the tongue ever since she was two years old. The tumour appeared after the measles, and had when it was removed a few years ago attained the size of a large nut. It was soft and without a capsule, and seemed to be an exuberant growth of the normal tissue of the tongue. He had treated a case of tumour of the tongue some years back by means of a ligature, but the strings took fourteen days to come away, and although disinfectants were used, the discharge was very offensive. In the present instance chloroform was given, the patient gagged, the tongue drawn forward by means of a ligature, and the tumour removed by the knife. Ligatures broke away and the pain was excessive, coming principally from these vessels; the actual cautery at once stopped the bleeding, and the general bleeding was stopped by iced water. The wound of the tongue was almost absolutely healed.

THE CONTAGIOUSNESS OF TYPHOID FEVER.

The following communication addressed to Dr. Routh was read from Mr. Richard Eager, M.R.C.S., of Guildford :—

Dear Sir,—A few years ago a case of an analogous character to the one you instance occurred to myself. A female domestic servant, after some days of slight indisposition, was seized at night with rigors, headache, over increase of temperature, and other indications of fever. On the following morning she was sent to her own home at a village abont three miles distant from this town, the attack developed itself into one of typhoid. She was nursed by her mother and a younger sister. The disease was severe, and convalescence did not commence until after a month's time had elapsed. Scarcely had this began when the mother was seized with the same form of disease, and in two or three days the sister succumbed. An elder sister returned home to assist her family in this trouble, and her nursing was supplemented by a charitable neighbour before convalescence was established, in the two latter cases the father and this neighbour both contracted the disease.

Now here were four cases of typhoid originating in a house into which one case had been previously imported from a distance, and that too in a village composed of about thirty houses spread sparsely over a very considerable area. The hygienic condition being fairly good, the cottage an old one, but roomy and substantially built, well ventilated by ill-fitting doors and windows. The privy is thirty or forty yards distant from this particular house, as well as from the well, so as to negative a suspicion of fæculent sewage contamination. The well is in the chalk, having a superstratum of gravel of a foot or two in thickness, and in the absence of an analysis the water is pure to smell, sight, and taste. The drainage of the house is good, and consists almost entirely of sink water, which runs off by an open surface drain. Nor are there any stagnant gutters such as sometimes exist in close contiguity with the habitations of country villages. The houses are not shrouded by trees, as the village is in an open down country, and the free currents of the atmosphere are unimpeded. The cottages are almost all detached, situated in gardens. I have known the parish for many years, and for a considerable time was "parish doctor," during which I never knew a case of typhoid occur, nor have I since heard of the existence of such a malady in it. To what source are we to trace these four cases if not to contagion? The contagiousness of typhoid is, I know, very generally denied, but with the experience of the foregoing cases, amongst others of a less convincing character which I have witnessed, I must confess that my mind is impressed with an affirmative conviction on the subject, for the expression of which I have been from time to time considerably snubbed by my medical friends and neighbours.

I am, dear Sir, &c.,
RICHARD EAGER.

Guildford, 31st December.

ADDRESS OF CONGRATULATION TO H. M. THE QUEEN.

The announcement from the chair that a special meeting of the Council had been called and a sub-committee chosen to draw up an address of congulation to H. M. the Queen on the recovery of H. R. H. the Prince of Wales was received with much applause.

THE PATHOLOGY AND TREATMENT OF NEURALGIA AND ITS KINDRED DISORDERS.

DR. JOHN CHAPMAN, the author of this paper, having explained that by the words kindred disorders he intended to denote a large group of morbid phenomena, some one or several of which may be associated with the pain, and therefore are sometimes designated the complications of neuralgia, he showed that no pathology of the disease which does not give a complete and consistent rationale of their production can be accounted satisfactory. The doctrine which he believes adequate to explain all the phenomena of neuralgia, which he said indicates a successful method of treating the disease, and the truth of which seems to be proved by the results of its practical application, he stated in the following proposition :—

1. That pain, whatever may be its exciting cause, and whatever may be the structure in which it occurs, is like ordinary sensations, a phenomenon of functional change in the sensory centre, into which the afflicted nerve is rooted.

2. That the nature of the functional change denoted by ordinary sensations, and the nature of that denoted by pain are essentially identical. The difference between the two being only a difference of degree of rapidity or intensity with which the change occurs.

3. That pain, like ordinary sensation, is of various degrees of intensity, and that whereas pain denotes a more rapid functional change in the affected sensory centre than occurs during ordinary sensation, the successively higher degrees of intensity of pain are expressive of successively higher degrees of rapidity of functional change in the functionary sensory centre.

4. That whereas an indispensable condition of these functional changes in the sensory centre, which are comprised within what may be termed the ordinary sensory scale, is a normal supply of arterial blood in order to provide for those transformable changes which are at once chemical and nutritive, and which constitute the groundwork and possibility of functional change, so a supply of arterial blood greater than normal is an indispensable condition of those more intense functional changes in the sensory nerve centre comprised within the wide range of what may be called the neuralgic, or more conveniently and perhaps more correctly the algic scale.

5. That pain is not necessarily a morbid phenomenon; that in its beginning it is rarely if ever so in otherwise healthy organisms; but that if in such organs the operation of its exciting cause will induce in the affected sensory centre a habit of morbidly intense functional activity, so that at length when that habit is generated, it will persist even after its cause is removed.

6. That a neuralgic habit thus generated may be transmitted hereditarily; and though it may remain latent during a considerable time, may be suddenly lighted up by some exciting cause so slight as to escape observation, and thus constitute in the second generation what is sometimes designated idiopathic neuralgia.

The general doctrine expressed in these propositions is "mutatis mutandis" applicable, Dr. Chapman maintained, to the several phenomena constituting the complication of neuralgia, and which consist generally of disorderly action of muscles—voluntary and involuntary, of disorderly actions of glands, and of disorderly processes of local nutrition. He arranged the whole class of neuralgias into six groups as follows :—First, these cases in which there is apparently no complication of any kind, and in which the pain having no obvious cause, is referred to some parts of the periphery seemingly healthy. Second, these cases which, like the cases constituting the first group in respect to the absence of any morbid phenomena at the seat of pain, are distinguished from them by having an obvious or assignable excitive cause, the pain being referred either to the seat of cause, or to some part of the periphery more or less remote from it. Third, cases like to those forming the first and second groups, without the additon of morbid phenomena of the voluntary muscular system, chiefly but not necessarily at the seat of pain. These phenomena consists of cramps or tonic spasms, twitches, jerks, and other convulsive movements. Fourth, cases presenting besides the pain and disorderly muscular action just mentioned, some one or more of the following phenomena:—Pallor, coldness, and anæsthesia of the neuralgic area; partial paralysis and atrophy of the affected nerves, amaurosis, paralysis of various cerebral nerves. Dilatation of the pupils, partial atrophy and enfeeblement of voluntary muscles, constipation of the bowels, deficient menstruation; certain indolent ulcers to which the epithets "neuralgic and cold" have been applied. Fifth, cases which, while presenting any of the phenomena characteristic of each of the preceding groups are distinguished by symptoms of excessive action. The glands or glandular surfaces which are excessive, being seated within or near the region of pain. These symptoms comprise lachrymation, excessive nasal secretion, ptyalism, bronchorrhœa, nervous flatulence, diarrhœa, excessive secretion of urine, seminal emissions, leucorrhœa and unilateral sweating over circumscribed areas. Sixth, cases which while presenting some of the characteristics already described also present symptoms of local inflammation which manifest itself in various shapes, the peculiarity of the phenomenon in each case being dependent on the special character of the structure in which it appears. The following were given as examples of these complications:—Swelling or hypertrophy of the neuralgic area; neuritis; hypertrophy of the affected nerve, herpes, changes in the development and colour of the part, photophobia, ophthalmic iritis.

Dr. Chapman adduced facts and arguments in support of his doctrine that the proximate cause of neuralgia itself consists in hyperæmia or excessive nutrition of the sensory root (which he called the algic centre) of the affected nerve, that a like condition of the roots of the voluntary motor nerves affected is the proximate cause of the phenomena characteristic of Group 3. That a like condition of the affective vaso-motor (called by him negative motor) nerve centres is the proximate cause of the phenomena characteristic of Group 4. That a like condition of the cerebro-spinal motor nerves (called by him positive motor) distributed to glands and glandular surfaces is the proximate cause of the phenomena characteristic of Group 5; and finally, that a like condition of the roots of the so-called "trophic" nerves also termed by him *positive motor* nerves, is the proximate cause of the trophic phenomena constituting the main features of Group 6. Assuming the general correctness of the pathological outlines which he presented, he affirmed as a general therapeutical principle that those agents which can be used with the greatest effect in order to excite a sedative influence on the nervous centres, the hyperæmia of which gives rise to the pain and complications in question are precisely those which are likely to exert the greatest remedial power. He then showed that the treatment which most thoroughly exerts such an influence, and which as he believes is capable of effecting the largest proportion of cures, consists in modifying the temperature of the spinal region by the application of heat and cold. This method of treatment, he said, "possesses the great and peculiar advantage of being able to impart sleep to the weary sufferer without poisoning the blood, without even clouding the brain with a noxious influence, without constipating the bowels, and indeed without disturbing any of the orderly functions of the organism, and unlike morphia and other narcotics, this remedial power is capable of annulling pain without creating in the algic centre a tendency to become after the sedative influence has ceased to operate, more hyperæmic, and therefore more capable of pain than before. The paper was concluded by a general explanation how to apply both cold and heat along the different parts of the spine in order to produce the specifically sedative effects intended in each case; by warnings to avoid certain dangers which are incident to the practice of the method by those who without the exercise of adequate caution and forethought, or without adequate study of the principles which underlie it, presume to use it as if it were a mere empirical nostrum, and by a brief discussion of several cases exemplifying in a signal manner the efficacy of the method in question in treating neuralgia, as well as its kindred disorders, and especially in inducing sleep.

The President thanked Dr. Chapman for his interesting and ingenious paper, in the discussion of which Dr. Thorowgood, Dr. Douglas Powell, Mr. McDonagh, and Mr. Brudenell Carter took part, and the Society adjourned.

THE SURGICAL SOCIETY OF IRELAND.

Mr. Croly narrated—

TWELVE CASES OF "BENT KNEE-JOINTS,"

which will be found at page 91.

Dr. Croly remarked that Dr. Cruise had told him of a case in which a bent knee had been treated by E. Hutton, by taking out a wedge-shaped piece of the femur, but the result had been very unsatisfactory.

Dr. Barton asked whether Mr. Croly had succeeded in getting back the tibia condyles below the femoral condyles because, in his opinion, the result could not be very satisfactory otherwise.

Mr. Stapleton had seen useful legs made in cases much more deformed than those related by Mr. Croly, even to so great a degree that the heel struck against the buttock. In some of these cases the disease did not commence in the knee-joint at all but by necrosis of the tibia. In one in which the condition was so bad that the propriety of amputation was debated, he had advised against operation and the result of the conservative method was very satisfactory. He (Dr. Stapleton) had had cases in which forcible extension and tenotomy had been performed, but he much preferred gradual extension. In some cases in which a very slight degree of motion existed the result had been beneficial, but he considered that the advisability of forcibly extending in the case of a child nine years of age was very doubtful, as the consolidation of the epiphyses had not taken place at that time. In most of these cases there was some shortening and he thought that condition was not to be regretted as it gave elasticity to the limb, and was compensated for by the motion of the pelvis. Dr. Stapleton disapproved highly of resection of joints in such cases, believing that they could be much better dealt with by the less tedious procedure.

Dr. Henry Kennedy noted the case of a man who, after a severe fever had acquired complete rigidity of the limbs, but after very persevering treatment by traction and rubbing, complete use of the limbs was recovered.

Mr. Edward Hamilton thought no question could exist as to the adoption of Mr. Croly's treatment. He had seen a case in which a wedge-shaped piece of bone had been removed, but the result was not encouraging, as diffuse inflammation set in and the patient died.

Dr. Roe said that the case of Mr. Croly's, which he had seen, was one of the least promising he had ever seen.

Mr. Fleming asked can we conceal from ourselves the fact that the epiphysary line was involved in the disease, and he had seen a case in which a displacement had taken place at the line. He considered that the small amount of shortening which appeared in Mr. Croly's cases was a strong argument in favour of tenotomy over excision.

Mr. Croly, in reply, said he was never able to reduce the dislocation beyond a certain extent. He thought the amount of deformity was not an index of the amount of disease, for, in his experience, the greatest deformity existed in cases where little disease was present. The verdict as to forcible or gradual extension must be determined, more or less, by the amount of disease present in the joint. With regard to the amount of motion, Dr. Croly said that one of his cases could flex his leg to a considerable extent, and another had almost perfect motion.

CASE OF EPIPHYSARY FRACTURE.

An abstract will be found at page 97.

Mr. Stapleton had seen some cases of lacerated wounds in which there had been very troublesome bleeding.

Mr. Croly thought that the position of the fracture through the epiphysis so low down, was the reason why the vessels escaped rupture.

Mr. Hamilton still retained the opinion that there was usually scarcely any hæmorrhage in such cases. With respect to Mr. Croly's views he thought that the protection of the vessels was altogether due to the fact that the limb was thrown outwards.

Mr. Richardson observed that Mr. Hamilton's case was interesting in another point of view, namely, that the separated epiphysis of each femur carried with it a thin layer of bone from the shaft; and was illustrative of a character of these fractures alluded to by Cruveilhier many years ago, and to which this surgeon refers the crepitus which is occasionally felt in epiphysary fracture.

CONTRACT DRUG PURCHASING.

WE have reason to believe—certainly we have cause to hope—that the scandalous abuses which have been unveiled in connexion with the supply of drugs by contract to Irish Unions will not be forgotten by the Poor-law Commissioners or the Profession.

The discoveries which were made before the Commissioners took action, and the facts which were publicly put forward at the time, may be epitomised in the statement that the Irish Union Drug Contract System is a wholesale system of fraud on the sick poor if not on the ratepayers, and that the guardians are neither competent nor, in many cases, willing to put an end to it as long as the appearance of providing proper medicine for the poor can be kept up by supplying them with the greatest rubbish at the smallest price. We felt it necessary when the proposal of the Poor-law Commissioners to establish a monster drug shop was on its trial to oppose it strongly on its merits, but we nevertheless thoroughly recognised the propriety of some such action, and we are now even more fully alive to the necessity of establishing a system of supervision and inspection.

That it is ridiculous and improper to make country petty shopkeepers or small farmers the judges of the purity or price of drugs *va sans dire.* But we maintain that the purchase by contract is in the case of drugs or of any matter which fluctuates in price as they do, a wrong and injudicious system. We find in the *Chemist and Druggist* of this month the following comparative table of the prices of certain drugs from one year to another :—

	Jan., 1872.				Jan., 1871.			
	£	s.	d.		£	s.	d.	
Canthárides ...	0	7	6		0	4	6

„ „ yellow ...	„	0	1	9½	0	0	11¾
Iodine, *branded*	„		*none*		0	0	10¾
seconds	„	0	2	4	0	0	10½

We have moreover had before us for comparison the Drug Lists of Messrs. McMaster and Hodgson for this and last year, an inspection of which shows us that these fluctuations exist more or less in every article of Pharmacy. We select a few further illustrations of our meaning :—

		1870.				1872.		
		£	s.	d.		£	s.	d.
Potassii Iod.	lb.	0	12	6		1	19	0
Acid, Tart.	„	0	1	4		0	1	9
Opium	„	2	0	0		1	0	0
Morphia	oz.	1	1	0		0	11	6
Bismuth Alb.	lb.	1	1	0		0	13	6
Iodine	oz.	0	1	0		0	2	10
A. Murrhuce Opt ...	gal.	0	8	6		0	6	6
Hydragyrum	„	0	2	4		0	3	6
Fabæ Physostig ...		0	6	0	1871	0	2	0

It is thus obvious that a contractor who fixes his prices at the minimum which we know is his only hope of obtaining the contract from an Irish Union, *must* either defraud himself or the union, and we know which way human nature will look when such alternatives are exposed to view.

McMaster and Hodgson have been persistent in the effort to impress this view upon the public. Their trade list has grown corpulent in the effort, and we have reason to believe that consumers who buy for themselves and not for sick paupers, have evidenced their concurrence in so commonsense a view of the question.

◆

Notes on Current Topics.

Medicine and Pharmacy in Valparaiso.

A DECREE has been issued by the Intendant of Valparaiso, regulating the practice of medicine and pharmacy in the department, which appears to have excited a considerable amount of consternation amongst those most concerned. *The Pharmaceutical Journal* publishes an epitome of the decree, which orders that all "physicians, surgeons, phlebotomists, chemists, druggists, and midwives" who desire to practise their profession in the department shall give notice of their intention in writing, producing their diplomas at the same time. Notice is to be given of an intention to suspend practice, or to be absent from the department. Twice a year all those engaged in practice [query, physicians, surgeons, phlebotomists, chemists, druggists, and midwives], are to hold one or more meetings in which questions of public health are to be discussed, and in addition the medical men are to hold extraordinary meetings whenever so required by the authorities, in times of plague and epidemic, or other grave necessity. It is made compulsory for all doctors to submit to a weekly "turn," when two are to hold themselves in readiness to serve the public from twelve at night till seven in the morning, and this without remuneration, in case of the applicants being unable personally to pay them. With only sixteen doctors the "turn" would occur once in every two months. They are also in turn to attend daily at the dispensaries, or other public places, pointed out by authority, in order to lend professional assistance to the poor, and give them the prescription they may require.

The Oral Education of the Deaf and Dumb.

THIS subject was brought under the notice of the Society of Arts on the 17th inst., in a lengthened essay by Mr. Dasent, who communicated results of the adoption of the method advocated by him, which are very encouraging. In one statistical epitome of the subject he said that on an average, there are 700 deaf and dumb persons in every million of the inhabitants of the earth, so that there would be 200,000 of these unfortunates in Europe alone; and here it must be remembered that observation has shown that in mountainous countries—such as Switzerland and Savoy—the deaf and dumb stand in a much greater proportion to the rest of the people. In the canton of Berne, for instance, it is stated that in every 195 persons there is one deaf and dumb, which would raise the total in the million to 5,128. Roughly speaking, we may say that there are probably about 700,000 deaf and dumb on the surface of the earth.

If we come home to Great Britain, we find the rule still holding good as to the frequency of the deaf and dumb in hilly and pastoral districts. The northern counties of Scotland, and especially the Highlands, present the highest average, where the number rises to the enormous proportion of 1 in 196 of the population. The average proportion of the deaf and dumb to the rest of the population all over Great Britain is 1 in 1,660; in Ireland, it is 1 in 1,380 persons. At the census for 1851, 12,553 persons, 6,884 males and 5,669 females were returned as deaf and dumb in Great Britain; and in the twenty years which have since elapsed the number of those unfortunates has proportionately increased. It is curious to remark that all over the world, so far as statistics afford us any information, the number of males born deaf and dumb is considerably above that of females similarly afflicted. In Great Britain there are 121 male deaf mutes to 100 females. There still remains a fact which it is more important to note than any other connected with these unfortunates, that throughout the country a very small number of the whole amount of the deaf and dumb were returned as inmates at asylums or schools in 1851, when we have seen that the total number was 12,553, only 1,100 were returned as receiving special education. Nor is there any reason to suppose that this amount of pupils is much exceeded at the present day, though the total number of the deaf and dumb in this country has probably increased to upwards of 20,000.

The Reorganisation of the Army Medical Department.

THE Secretary of State for War has now before him Sir Galbraith Logan's scheme for the reorganisation of the Army Medical Department. *The United Service Gazette* understands that the chief feature of the proposed changes is the transfer of the regimental officers to the staff. It is stated that when two or three regiments are at the same station the number of Medical officers is superabundant to the wants of the sick, and that in peace time, when a battalion is not disconnected and the Medical strength divided, two officers are more than sufficient for the requirements of a corps of 700 men. It also understands that regiments are to have but one Medical officer in future, who will not be of it, but attached to it; that larger staffs will be kept at the several garrisons, and that the Militia surgeons will be called upon to give assistance in those localities where their aid may be necessary. It is understood also that in consequence of these changes a larger reduction of the lower ranks in the department will be effected by the application of compulsory retirement. The minor proposals, such as the transfer to the Army Medical Corps of the Permanent Regimental Staff, the re-institution of the old order of Medical clerk in general and garrison hospitals, and the abolition of the chemist's shop, which travels from place to place whenever a regiment moves, have, it is believed, all been approved.

Propagation of Small-pox.

The *Irish Times* remarks that in some cases the bodies of patients who have died of small-pox in Dublin have been given to their friends and conveyed away for burial to rural districts previously uninfected, and it had heard of two cases in which not only was the body brought down to a country parish thirty miles from Dublin, but "waked" in the manner best calculated to spread the disease. In many instances the authorities have refused to surrender the bodies of patients to be carried to the country, and have insisted on their being buried in Dublin, but the rule ought to be identical in all instances.

Thrombosis of the Internal Carotid.

A VERY curious case was communicated to the Academy of Medicine of Paris last week, by M. Verneuil on behalf of M. Richelot. The patient had received some apparently slight injuries by the overturning of a cart, and was the subject of violent hyperæsthesia and excitement, which culminated in furious delirium, and eventually in coma, and all the symptoms of death by hemiplegia.

M. Verneuil diagnosed rupture of a small cerebral artery with compression, but the autopsy proved that this forecast was quite incorrect. After a careful search a thrombosis of the internal carotid was found filled by a coagulum which extended through all the ramifications of the middle cerebral, and accompanied by extensive softening of the left temporal lobe of the cerebium.

Lincoln Asylum.

THE Lincoln Lunatic Asylum is essentially a middle-class institution, but is not self-supporting, as patients that pay 12s. or 15s. a week cost over 20s. An appeal is therefore made on its behalf, for it appears that the friends of these people would be unable to contribute more.

We agree with the *Lincolnshire Chronicle* "that it would be almost a cruelty to drive these people into pauperism," and we hope the appeal may be successful.

An Important Medico-Legal Decision.

WE commend to the consideration of the Poor-law Medical Officers' Association the judgment given in the Court of Exchequer, on the 20th inst., in the case of "Dyte *v.* The St. Pancras Guardians." It was there decided that the plaintiff was not entitled to recover under a contract for the breach of which he sued the defendants, for the reason that it had not been passed under the seal of the Board. This decision, though it doubtless satisfies the requirements of the law, conflicts strongly with the natural sentiment of justice. We cannot but applaud the courage and public spirit which induced Dr. Dyte to contest the question, and trust that the appeal made by Dr. Woodman in another column, for funds to indemnify him in the heavy expenses he has incurred in the public interest, will meet with a liberal response.

The Late Dr. Christot, of Lyons.

In December we published a translation of Dr. Christôt's report on the massacre of the Lyons ambulance. It is with deep regret that we have to inform our readers of the death of this distinguished gentleman, who at an early age had won high honours in his profession, and has been cut off so soon. It is a very great loss to the profession of Lyons, of France, and we may say—so brilliant was his career,—of the whole world.

Hindu View of Cholera.

Such is the title of a pamphlet bearing date 1871, printed by the Civil Service Supply Association, 16 Monkwell street, London, the author, Golab Sing, M.D. The title and the name of the author alike arrest attention. We almost expect to find the clearest proofs produced from the Shastras that cholera is but a term invented by the Ferringhee for *Kali*, the third person of the Hindu Trinity, the Regenerator, the Destroyer. Perhaps, however, we had better let Golab Sing speak for himself. Here, then, are a few shreds selected from the Hindu view:—"Man shows or passes into cholera at intervals; certain periods of freedom exist" (page 3).—"The great general fact of the cumulative or latent and natural capacity for diseased rates is seen very markedly in aboriginal races." "Different epidemics vary greatly, and the cases in any epidemic vary not less" (p. 4).—"Like in all other evolutions and states of being, phenomena 'overlap' each other."—"That typhoid fever should sometimes show in the East and West Indies are instances parallel with the facts that the shark and sturgeon overlap the modern forms of fish" (p. 5). Perhaps few, if any, will be inclined to deny his assertion, that "in India cases of cholera are always about in the native communities." In fact, we have an impression that we have heard some such thing as this before, but less certain are we in regard to the next great fact enunciated, namely, that "an unfolding of the order of the anatomical evolution or development of our vertebral or nervous segments would give a true basis for the classification of disease" (p. 6). Really we must not disclose all the gems of this Hindu view. The above are taken almost at random. There are lots of others, and the price of the work is sixpence.

Dermatology..

Professor Erasmus Wilson, F.R.S., will commence his lectures at the Royal College of Surgeons on Friday, February 2nd, at 4 p.m. This course, as we have already announced, will appear in the Medical Press and Circular.

The American Diploma Market.

The *Roscommon Journal* announces—as if it were an event for the county or parish to be proud of—that the local curate had received from the University of Philadelphia—Dr. Paine's sewing-machine, bill-printing, and doctor-making shop—a degree of LL.D., *honoris causa in absentia.* "Honoris causa," indeed! Perhaps "Dollaris causa" would be more appropriate.

A Discreditable Proceeding.

We learn from the *Chelmsford Chronicle* how medical services are regarded and valued by the Committee of Local Dispensaries. They charge the patients twopence per week each, and propose to make a profit of some £50 or £60 per annum out of the hard and gratuitous services of their Medical officers. They used to pay a trifling honorarium, but have sent out a circular asking the Medical men to undertake the work gratuitously. Only one has accepted this. He is the parish doctor that has been appointed. We hope now he sees how things are going he will resign, and take his part with his brethren, who have so properly refused to lower the Profession thus.

The evils of gratuitous Medical work have been fully exposed lately, and it is time such proceedings as this brought public odium on the Committee. Poor-law Medical men should certainly not forget how much they owe to their brethren, who have done what they could to improve their position. The Committee of the Chelmsford Dispensary no doubt fancy doctors' time and work are worth nothing. They ought to be taught better.

The Effect of Various Liquors on the Kidneys and Bladder.

M. Kraus, of Vienna, in the *Mouvement Medicale*, treating on this subject, says:—"Sparkling wines are very injurious, but not in respect of their carbonic acid, which assists materially the elimination of phosphates. Champagne not only increases the secretions, but, in an extraordinary manner, the phosphates; and the conduct of Medical men who advise its use in calculous cases is irrational and unjustifiable. M. Kraus's experience contradicts absolutely the solvent action of carbonic acid on concretions already formed. He considers that old beer is an unobjectionable drink, but that lately brewed liquor is injurious, because the fomenting particles penetrate the mucous membrane and give rise to a greater or less degree of chronic catarrh. English pale ale is open to the same objection, in consequence of its richness in alcohol and the great quantity of carbonic acid which it contains; but porter, if of good quality and age, is reported by M. Kraus to be unobjectionable.

The Power of Coroners.

The Society for the Protection of Women have taken up a painful case in which a coroner ordered a Medical examination of a woman to ascertain whether she had been recently delivered. The question excited some attention at the time, and a contemporary submitted the case to its legal adviser. He and now Mr. Giffard, Q.C., state plainly that the coroner had no power to issue such order. We were surprised at the time that Medical men should have been found willing to act on the coroner's precept, and still more at the question being raised as to its legality, as most lecturers on forensic medicine warn their pupils against such an assumption of authority. The order was never actually executed, as the suspected individual committed suicide. The Society, therefore will probably be unable to take any proceedings against the coroner, as its officers seem to desire.

The lesson is none the less clear, and we hope members of our Profession will be careful how they accept as legal any coroner's precept. It is to be hoped coroners will be more careful in future. That they had such a power we never imagined. It would be monstrous.

Liability of Lodging Renters for the Propagation of Infection.

In the Court of Queen's Bench, London, the case of Best *v.* Strap was heard before the full court. The question—whether it is actionable to take into lodgings persons who have just recovered from the small-pox, and so communicate the infection to the inmates of the house? The plaintiff kept a lodging house at Eastbourne, and alleged that the defendant, knowing that his children had just suffered from the small-pox, and were in such a condition as that other persons might catch the infection from them, brought them into the plaintiff's house fraudulently, concealing the fact, whereby some of the plaintiff's children caught the infection and died, and his wife became ill, and he was unable for a long time to let his lodgings. The defendant "demurred" to the declaration, on the ground that it did not appear that he was under any legal obligation to disclose the condition of his children or to prevent them from being brought into contact with the plaintiff's wife and children; nor did it appear that, although he might be aware of the condition of his children, he knew or had reason to believe that it would cause danger to others, nor that there was any legal obligation upon him to give notice of their condition. That it was to be assumed that the plaintiff was accustomed to let out his lodgings to, or for convalescents, without regard to the diseases from which they were recovering, and that his terms were adapted to the risk he ran.

The learned judges, apparently not being clear as to the ground of legal liability, whether it was necessary that there should be a fraudulent concealment or not, advised the parties to go to trial first and ascertain the actual facts.

Army Medical Officers.

Deputy Inspectors-General of Hospitals J. H. K. Innes, C.B., R. J. O'Flaherty, C.B., and M. B. Gallwey; Staff Surgeon-Major H. Kendall, M.D.; Assistant-Surgeons Fawcet Joynt, M.D., Anthony, M.D., and Molloy, and Staff Assistant-Surgeon E. C. R. R. Ward, embarked last week for India. Staff Assistant-Surgeon Royle has been placed on temporary half-pay for twelve months, on the recommendation of a medical board; and Staff Assistant-Surgeon Crean has been granted three months' sick leave; Staff Assistant-Surgeon Haile, from Netley, has resumed duty at Ballinrobe.

The scientific world will regret to learn that, owing to the state of Professor Huxley's health, he has been compelled to relinquish all work for the present. To recruit his health, he has gone to Egypt, from which country he is expected to return in the spring.

Dr. Benjamin W. Richardson's (of London) next lecture, to be delivered on Tuesday, January 30th, will be on "The Therapeutic Values of Ethylic Alcohol."

The late Miss Rushton, of Edgbaston, has bequeathed to the General and Queen's Hospitals, Birmingham, the sum of £5,000, in equal proportions.

The magistrates of Kent have just determined to erect a new lunatic asylum, capable of accommodating 1,000 inmates. The outlay will be from £150,000 to £200,000.

The *United Service Gazette* understands that in consequence of the requirements of the camp at Aldershot, where there is but one administrative officer of the Army Medical Department, an additional Deputy Inspector-General of Hospitals is to be appointed at once. This will raise the future number of this rank from 20 to 21.

A very unusual case of double attack of small-pox has occurred at Wolverhampton—A policeman was attacked with the disease soon after its outbreak there, but he recovered, and resumed duty last month. On Thursday week he was a second time attacked with the disorder, and is again suffering from the disease.

Dr. Humphry, professor of anatomy in the University of Cambridge, having made an examination of the young hippopotamus which had been sent to the museum by the authorities of the Zoological Gardens the day after its death, reports that there was a complete absence of disease, and that, in his opinion, the animal died because it could not take its natural food.

Professor Naquet, Dean of the Faculty of Medicine, and whose "*Principles* de chimie" have a world-wide celebrity, appears not to be very popular in the French Senate. On Thursday last he brought forward a motion for the confiscation and sale of the ex-Emperor Napoleon's property. He met with considerable opposition, was much taunted as to the circumstances to which he owed his appointment, and was finally coughed down, without any division upon his motion.

The notorious Brighton poisoner who has been reprieved on account of insanity, has an imitator at the East-end of London. Dr. Wheeler, practising in the Bow road, had a child brought to him recently, evidently suffering from the poisonous effects of belladonna, from whom the following was elicited: The child, an intelligent little girl of about ten years of age, was sent on an errand by its parents, when it was stopped in the street by a total stranger, a middle-aged woman, decently dressed in black, who offered it a cake. The little girl ate the cake, was seized with violent spasm and vomiting, and but for the timely intervention of the Medical man would undoubtedly have died.

A case of considerable importance was decided at the Court of Passage, Liverpool. A baker let his shop and concerns for a reasonable rent to one of his own trade anxious to commence business. After the new tenant had entered into possession, first his foreman, and then his two assistants, were attacked with small-pox. On examination, it was proved that the previous owner sold his establishment because two cases of small-pox, one of them fatal, had occurred in the bakery. He gave no notice to the incoming tenant respecting the fact that an infectious disorder had prevailed in the premises. The tenant now sued the owner for all costs and damages caused by the disease, as well as for the sum paid to purchase the tenancy and good-will of the establishment. The jury found a verdict for the entire sum, with costs.

Correspondence.

HOMŒOPATHY.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Disapproval of, or dislike to, a work, or a system, is a very insufficient preparation for its just and powerful criticism. Criticism to carry any weight with it, must prove its author to be himself acquainted, by observation and examination, with the merits and demerits of the matter criticised. Dr. Pascale, in your Journal for the 10th instant, has fallen into the very common error of many who have gone before him, of mistaking zeal for knowledge, and consequently his attack on Homœopathy in your last number is very feeble, though possibly made with all the force he possesses. If writers against Homœopathy were to go "into training" before attempting their task, their efforts would have greater success.

If, for instance, Dr. Pascale had studied Hahnemann's works, and had then read some such criticism on them as is contained in Dr. Sharp's 13th Essay in his "Investigation of Homœopathy," (*a*) he would have possessed far more stones in his sling, and would have had the advantage of appearing as a fair critic. Or, if he had taken a different line when attempting to criticise Hahnemann's experiments with cinchona bark, and had studied the subject, he would have avoided the anachronism by which he speaks of Hahnemann's experiment as having been made with quinine; and have also learnt that bark and quinine are credited by Pereira and others with inducing febrile symptoms and disturbances of the nervous system, which present no little similarity to those induced by malarious poisons. Had he still further inquired into the diseases afflicting the workers in quinine factories, he would, at least, have suspended his criticisms until he was more thoroughly learned in the physiological effects of quininism of the drug.

Now, I am not about to take up the cudgels either in favour of or against Homœopathy. Like all other systems, it must stand or fall by its own merits, but these must be fairly tested by those writers who assume the part of medical critics. It is easy, in 1872, to criticise the medical theories of 1789, and to prove Hahnemann's works to be full of "unproved assertions, illogical arguments, fanciful speculations, and obvious contradictions." (*b*)

But for all that we may find them like a diamond-field, worth sifting for the truths that lie among much useless material.

We may regret the axiom "similia similibus curantur" *as a law*, and yet find it of use as a guide.

It is a true and fair criticism that says if "similia similibus curantur" be a law, then the dose which we give to cure a disease under this law must be as large as the dose which causes the "similar" to the disease.

Hahnemann himself denies that such a dose would be curative, but says, on the contrary, that it will aggravate the disease. This is common sense, and it does away with the logical action of "similia, similibus curantur." It condemns Hahnemann out of his own mouth. For example,—if twenty grains of ipecacuanha be needful to cause vomiting, we ought on the doctrine of "similars," logically administered, to give twenty grains of ipecacuanha to cure it. This dose would frighten any disciple of Hahnemann, and only an infinitesimal or very small dose is given in such a case; but an infinitesimal or small dose *won't cause vomiting*—therefore, where is the similarity?

If Dr. Pascale had taken that line of argument, his paper would have had a point in it as a criticism which it altogether lacks.

The discovery by Hahnemann of the direct relation between the physiological effects of certain drugs and the pathological conditions of certain diseases, will nevertheless prove a mine of curative wealth to the thoughtful and painstaking physician.

It ought to be of some practical use to a physician to know that medicinal *drugs possess more than one action*. That a narcotic can also be used as a stimulant; that a paralyser can also be used as a tonic—that, in fact, the behaviour of a drug depends much upon the dose given, and little upon its classification under the head of narcotic, or stimulant, or laxative, or emetic.

The great practical lesson we may learn from Hahnemann and his disciples is, that *the small dose of a drug has an exactly opposite effect to the large dose*. Thus, opium, which constipates in a large dose, cures some forms of obstinate constipation in a minute dose.

Ipecacuanha, which causes vomiting in a large dose, cures vomiting in a minute dose.

Arsenic, which causes vomiting and watery diarrhœa in a large dose, cures watery diarrhœa with vomiting in a minute dose.

If we know well the effects of a large, full dose of a medicinal drug, we can predicate, with certainty, the effect of the small dose, which is exactly opposite to it. If we know that twenty grains of ipecacuanha will cause vomiting, we know that frequent doses of the 10th or 20th of a grain will cure idiopathic vomiting when arising from stomach derangement. If we must hazard a theory to explain these facts we should say, whatever medicinal drug *paralyses* a certain tract, organ, or part of the body (when given in a sufficiently large dose), will be found to *stimulate* the same tract, organ, or part of the body if given in a small dose. Hence, if a tract, organ, or part of the body is idiopathically lowered in vitality by disease, the medicinal drug which exerts a physiological action on that tract, organ, or part of the body, should be given in a small dose in order to cure it. Dr. Sharp (above alluded to) has published some interesting essays bearing on the localised actions of medicines, which he calls organopathy. If his theory be true, it will form a good basis for a scientific investigation of the further theory of specific drug stimulation indicated above.

This apparently antagonistic action of drugs is best illustrated by a study of the effects of alcohol. A very large dose of raw brandy would have no stimulant effect, but at once prostrate the drinker, and narcotise him to death; but a small quantity of brandy and water both stimulates and excites the weary and exhausted traveller.

True cure-work is not to be forwarded by the battles of rival sects, each doing his best to discredit the efforts of his neighbour; but just criticism, aiming at the separation of truth from falsehood, at purging away the dross, and refining the gold, should be equally acceptable to all true labourers in the great field of medicine.

Yours, &c.,

WM. BAYES, M.D.

DR. DYTE.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

DEAR SIR,—Dr. Dyte's case (as you probably know) has been reheard, *in banco*, and the plea of the St. Pancras Guardians, that they never set their common seal to his appointment, has been allowed by the judges. No doubt their lordships' decision is legally right. For myself, I anticipated no other result—but the shallowness of the plea is so obvious, that I feel persuaded there are many will still gladly subscribe towards indemnifying Dr. Dyte from his loss, and the costs of the action. Only about £120 have been received. Between £300 and £400 will at least be necessary. I shall therefore still be happy to receive subscriptions.

Yours faithfully,

W. BATHURST WOODMAN.

6 Christopher street, Finsbury square, E.C.
January 26th, 1872.

(*a*) Groombridge and Sons, Paternoster Row, London.

(*b*) See Sharp's 13th Essay, p. 328.

DR. CARPENTER AND THE ROYAL SOCIETY.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—At the Chelsea Literary Institution on Friday, January 12th, we had a lecture on "Spiritualism," with a discussion after the lecture. On the following Friday, January 19th, as seen in the *Telegraph* and other papers, Dr. Carpenter favoured us with a lecture (an oft-told tale) on the "Phenomena of Spiritualism," and perhaps very properly refused discussion with the spiritualists, on the ground that there was "nothing in common between them," although as a paid lecturer, probably it would have been better to have acceded to their request? But it is of certain disclosures connected with the Royal Society, that I have to complain, I have no sympathy with the mesmerists and spiritualists, nor do I believe in the new force, passing from animate to inanimate bodies, as supposed by Mr. Crookes, but knowing as I do of some able men who have reported on some of the phenomena of so-called Spiritualism, that with all its falsities and assumptions, there is something about it that is not quite understood, I think that Mr. Crookes *(who disbelieves in Spiritualism)* is engaged in a very laudable investigation, although at present I see no evidence of the "pyschic force" he describes.

Dr. Carpenter in his article on "Spiritualism and its recent Converts," in the *Quarterly Review*, for October, p. 348, twits one gentleman, Mr. Varley, for not having been admitted to the Royal Society, when at the very time this gentleman was a Fellow, and he calls Mr. Crookes the "Specialist of Specialists," although Mr. Crookes shows in his pamphlet, page 13, that irrespective of his discovery of the metal Thallium, his labours in science have been quite as varied as those of Dr. Carpenter.

But now for the grave charge that I bring against Dr. Carpenter, and it is quite time it should be exposed; because its frequent repetition by the President Elect of the British Association (a paid lecturer) will neither redound to his credit nor to that of the Royal Society.

Dr. Carpenter, at the conclusion of his lecture, said "that two papers by Mr. Crookes on psychic force had been rejected at the Royal Society; one was unanimously rejected the night before his lecture, and then he proceeded to test one of Mr. Crookes' experiments described in this *private* communication and to show the fallacious inferences that Mr. Crookes had drawn from it. Surely, Sir, you and your readers will see that a great breach of trust is involved in these disclosures, and also the unfairness of selecting one experiment out of many for the purposes of crushing an adversary, and I may add the cowardice after such attacks, of refusing all discussion?

I have not the honour of knowing either Dr. Carpenter or Mr. Crookes, but I know Sir, that the Royal Society) the fellowship of which, according to Dr. Carpenter, appears to be the only test of intellectual worth) looking to its past history, is not quite immaculate, and Dr. Carpenter will pardon me for adding, that a society as the charter states, that was formed to glorify God s works—that rejected the late Mr. Yarrell, because he was engaged in trade, and that compels a commoner to have his name suspended for ten months before he can be ballotted for, and that admits one of the aristocracy (so called) on the night of his appearance, is not a body that all the world would have confidence in?

I need scarcely say that I have never coveted the honour of this Fellowship, and if such revelations from private papers, as those made by Dr. Carpenter, are approved of by the Council, others like myself will prefer to be in the shade, and to use the words of Dr. Carpenter in the *Quarterly Review*, as applied to Mr Varley, then a Fellow, would rather labour under the imputation, that "his scientific attainments are so cheaply estimated by those who are best qualified to judge of them, that he has never been admitted to the Royal Society."

I am, Sir, yours obediently,

EDWARDS CRISP, M.D.

29 Beaufort street, Chelsea, January 24th, 1872.

CORRECTED NOMENCLATURE.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—It is a long time since I had the honour of correcting some medical nomenclature through the medium of your columns, in respect of *trachinia* and its plural *trachiniæ*, as well as the name of the disease itself, which I argued should be properly termed *Trachinosis*, and I believe it was acknowledged that I was correct.

Emboldened by this success, I desire under your banners to do battle against that misnomer in natural history, in the singular *octopus* which is faulty, and the plural formed from it *octopi* which is abominable; almost as bad as *omnibi*, which I once heard, many years ago, not from a bishop's mouth but at his lordship's table, when, humble curate as I then was, it struck me at once what a goose the man is! why does'nt he at once say in honest English *omnibuses*? But we had just been conversing on railroad *termini*, and consequently *mon ami*, who was well up in the Natural History of Snobs, judiciously inferred, because of the similar *exit in us*, that *omnibi* must be the plural of *omnibus*, just as *dominus* nom. sing. makes nom. plur. *domini*, and *terminus termini*, quite correct, and ergo *omnibus* as a nom. sing. would result in *omnibi* as a nom. plur. I said nothing, only I *thought* what is Latin for a goose? *Anser* that.

But to return to my present grievance: the term *octopus*, which in Greek letters would be 'Οκτώπους, and literally translated is *eight-foot*, ought in the plural to be *octopodes*, but that would be too learned without conveying the correct idea. We mean by the improper term we use a creature with *eight feet*, that remarkable cuttle, which in some parts of the world is gigantic, having *eight tentacula* arranged on its head, four on each side of its powerful sucker, wherewith to seize its prey and hold it fast and suck it out, as the money lender, at from 30 to 60 or 100 per cent., sucks his victim and absorbs him quite. The marine animal, not belonging to genus *homo*, is classed with *cephalopods*, mollusks whose feet are at their heads, a term perfectly right in its Greek and English plural, *πούς a foot, πόδες feet*, and at once showing us that what we badly name an *octopus* we should call an *octopod*, and then the plural *octopods* would result from it in due form and order. Then a man might write to his friends and say, "I have just seen an *octopod* in the British Channel, but it was a baby in comparison of the *octopods* which are common in the tropical seas."

I have only to confirm my argument from the name of that remarkable but unfortunate man *Œdipus*. What scholar would ever think of calling his sons the *Œdipi*? nor could they be termed *Œdipodes*, as we speak of the *antipodes* which is tolerable. The descendants of *Œdipus* would be *Œdipoeidæ* or something in that way, for *Œdipus* is literally *swollen foot* and has no natural plural. Consequently *octopus, eight footed*, can have no plural of its own, and if we attempt it, the result is ridiculous. Make it *octopod* and the addition of a single letter gives us a logical and agreeable plural. But I protest against *octopus* as incorrect, and against *octopi* as horrible.

Should you encourage me by the insertion of this letter in your next, I should much like another day to submit my ideas on *hippopotamus* and *hippopotami*, which belong to the same family of misnomers as do these ill-named cuttles.

I enclose my card, and am, your faithful servant,

PHILOLOGUS ORTHODOXUS.

Sutton, Surrey, 27th January, 1872.

Foreign Medical Literature.

MEDICAL JURISPRUDENCE.

DR. ALFRED TAYLOR'S TEST FOR BLOOD BY MEANS OF THE TINCTURE OF GUAIACUM, AND ITS REACTION WITH ANTOZONE.

(Translated expressly for the MEDICAL PRESS and CIRCULAR from the *Union Médicale*, by F. M. LUTHER, M.D.)

IN 1861 Schönbein discovered that peroxide of hydrogen or antozone had no action upon tincture of guaiacum, but that this re-agent gave the resin a blue colour under the influence of blood-corpuscles in a state of solution.

Two years later the Dutch chemist, Van Deen, turned this observation to profit; he showed that every time that blood was treated by tincture of guaiacum and ozonised essence of turpentine, a blue colour was obtained, which he considered as characteristic of blood.

Shortly after Dr. Liman (of Berlin) formulated conclusions somewhat different from those of Van Deen. When this process gives a negative result, one may conclude with certainty that there is no blood. When the test gives a positive result, a blue discolouration, one cannot affirm that blood is the cause of it, unless other reasons come to corroborate that conclusion.

A long discussion is pursued by the author on all the points of detail that this fact implies. The first is the interpretation of the change of colour in the resin; the author attributes it to oxidation. This oxidation the colouring matter of the blood is incapable of producing by itself; it effects it in the presence of a body containing antozone, the latter, moreover, being by itself in its isolated state without any oxidising action upon the resin.

It appears to be one of the facts best established by this work, that exceedingly small quantities of blood, inappreciable to ordinary chemical tests, may still be discovered by this process. And it may be concluded, from the positive and negative results obtained by Taylor in his experiments, that blood washed to a state of extreme dilution may be easily detected by this test. It remains to be determined if the blood stains may not at a given moment lose the property of oxidising tincture of guaiacum; the same author thinks that after a long time, ten years at least, dried blood still possesses all its oxidising power, and is readily detected by this process. This latter result, however, has not been obtained by all experimentors.

The red colouring principles of vegetables differ from the colouring matter of the blood: in the presence of peroxide of hydrogen, they do not change the colour of tincture of guaicum. This applies to the colouring principle of cochineal.

Still the uncertain character of a reaction which does not belong exclusively to the blood, nor especially to the colouring matter of the blood, must render one cautious in the conclusions to be drawn from such an examination; and Taylor recommends that his process should only be applied after having interrogated the stains by means of known chemical tests; by the microscope and particularly the spectroscope, the result from which have such a great significance, and by means of which the minutest portions of the suspected solutions can be availed of for examination.

◆

CURRENT LITERATURE.

Among the many works that we are accustomed to group under this title not a few though small are of considerable value. Moreover, this heading gives us the opportunity of mentioning, now and again, periodical works, and occasionally new editions of works previously reviewed in our columns. Of the former we have to announce the appearance of the two half-yearlies which are published with their usual punctuality, and contain as usual, selections from our columns and those of our contemporaries'.

We take this opportunity of drawing attention to the *American Journal of Obstetrics*, which is the representative of the specialty to which it is devoted, and one of the most ably conducted Quarterly reviews.

America continues to take a great place in this class of journal, at the head of which the great work of Dr. Hays, the *American Journal of the Medical Sciences* still holds its ground as our quotations have often proved.

The *Dublin Quarterly* has now become a monthly journal, so that Dublin and Edinburgh each possess a monthly, and London has two, the *Practitioner* of the same character as the others, and the *Doctor*, which has struck out an entirely new path,—giving in a few short paragraphs the pith of the other periodicals, both British and Foreign, and forming a capital supplement to the weeklies.

We turn now from the periodicals to several productions that demand a few words in this place.

Mr. Spencer Wells's *Note Book for Cases of Ovarian and other Abdominal Tumours*, 1871, Churchill. Mr. Wells has during the last two or three years kept a separate book for every patient who has consulted him for ovarian disease: and has found this so convenient that he has had the questions and diagrams printed in the form of a little pamphlet of twenty-five pages. It is well worth while for any practitioner who has such a case under his care to send for this *brochure.*

Annual Report of the General Health Committee of Salford, 1871. It appears from the above Report that there are 19 common lodging-houses in Salford, containing 61 sleeping rooms, with accommodation for 261 persons. These have been improved of late and only 43 wooden bedsteads remain The general health of the inmates has been good. The Committee recommend the extension of the Tub-closet system. All scullery and bath-room drains have been as far as possible disconnected from the sewage drains. All inlets to the drains should be internal to the houses.

Report of the Ladies' National Association for the Repeal of the Contagious Diseases' Acts, Liverpool, 1871. This is a society, of which the Hon. Sec. is Mrs. Butler, and which has Mrs. Jacob Bright and Mrs. McLaren on its committee. It seems that this Ladies' Association is in close alliance with the National Association for the same object in London. In page 7 the Report says:—

> "We hold it a dangerous precedent to allow any government, most of all one professedly liberal, to assume that the good name and personal rights of women are subordinate to the necessity of protecting soldiers from the physical disease which is the consequence of licentious indulgence. The issuing of a Royal Commission proceeds on this fact as an assumption, and we therefore urge our friends everywhere, emphatically to protest against it, as they would against the shameful Acts themselves."

We perceive that upwards of £1,000 have been subscribed during 1871 to this Fund.

Modern Hydropathy, with remarks on Baths, including the Russian Vapour and Electrical Steam Baths in acute and chronic diseases. By James Williams, M.D. London, Baillière, Tindall, and Cox, 1871.

The author of this pamphlet says "that in former editions he has sought the co-operation of his professional brethren in testing the merits of Hydropathy, but with little success. He gives as the results of his own experience, the deliberate opinion that the hydropathic physician depends too exclusively on the action of water upon the surface of the human body, and altogether loses sight of the respiratory tract as an important part of the animal economy. Majendie has shown that medicated vapours and gases pass far more rapidly into the blood through the lungs than by any other means, and thus change its chemical constitution." There can be but little doubt that far too little attention has been paid by the present race of Medical men in this country to what is styled Hydropathy. So much is this the case that it is only now that cold baths are coming into vogue for the treatment of typhoid fever and rheumatic pyrexia, instead of the absurd prescription of large quantities of brandy and wine, which has been so long praised by the disciples of Dr. Todd. We are much mistaken, or there is a coming crusade likely to be made against that school and its tenets, and that the doctrines of the best hydropathist will soon obtain a fair and impartial hearing. Fresh air, cleanliness, abstinence from alcohol and tobacco, exercise and simple food, are all hydropathic recommendations and, *certes*, are not bad medical art.

Tobacco.—An Essay, by HENRY GIBBONS, M.D., of San Francisco, California, Prof. of Mat. Med. in Ireland Medical Coll. London, Burns, Southampton-row.

DR. GIBBONS says that medical writers, without exception, describe tobacco as a *poison*. The mouth and throat are injured by smoking. The "smoker's sore throat" results from this cause. Cancer of the lip is produced by pipe smoking. The voice is affected by smoking. The stomach and digestive organs are disordered by it, dyspepsia and constipation are caused by it. The complexion is rendered sallow, cough is often produced by it. The heart beats often irregularly in smokers. The brain and nerves suffer most from tobacco. Amaurosis, timidity, palsy and insanity are traceable to its use. It is said to favour, says Dr. G., perforation in typhoid fever; it diminishes virility. The Spaniards and Turks have smoked away their energies. In New England, both smoking and drinking were forbidden almost entirely, to the great advantage of the population; prize-fighters abstain from both, and in Berne, Switzerland, tobacco was recently forbidden to all young men under fifteen. The French Minister of public instruction lately found that the non-smokers were far the best students. In the Ann. Rep. of the Mass. Gen. Hosp. for 1843, eight cases of insanity are ascribed to the excessive use of tobacco. Smoking tends towards slovenliness and is "the bane of good manners," says Dr. Gibbons. "Writers are wont to dwell with enthusiasm on the merits of tobacco as a luxury to the poor; they should bear in mind that the husband and father is the only one of the family who usually enjoys the luxury." It does no good. There is certainly much truth in the crusade against tobacco in the present day. We notice that in France, Dr Joly, in London, Dr. C. Drysdale and others protest against tobacco as a poison, and we certainly believe that more can be done by the medical profession by attending to the habits of the citizen, than by merely prescribing drugs or performing surgical operations.

A Contribution to the Treatment of the Versions and Flexions of the Unimpregnated Uterus, by E. CUTLER, M.D. Boston, 1871. This is an excellent pamphlet on a difficult subject, enriched with many diagrams of the uterine organs and the pessaries recommended by the author. We do not remember to have seen a clearer exposition of the subject in any work, and can heartily recommend this for perusal.

What the People say about the Children and what the Children say about Canada, by MARIA RYE. (London, Wade, Tavistock-street, 1871). Miss Rye has kindly superintended the emigration of some 460 girls between the ages of 9 and 13 to Canada, and in this pamphlet publishes their account of their new homes. Over 400 families in Canada have applied to her to send them more. Miss Rye has deserved well of her country.

Emphysema of the Lungs, by DR. BERKART. London, 1871, Churchill, pp 15. Dr. B. thinks well of the inhalation of compressed air in emphysema; but this gives, he says, only temporary relief. A better result he contends, is obtained if emphysematous patients are allowed to expire into an atmosphere the pressure of which is from 4 to 8 inches of water less than that of air. Such instruments as will effect this (Hawksley, Blenheim-street) have been designed by the author, and are recommended to be used twice a day for a quarter of an hour each time for some weeks.

Report on Sanitary Committee on Tea. 1871. This is an interesting account of the adulteration of tea practised by some London merchants, by Dr. Letheby and others. One specimen seen, called Fine Moning Congou, consisted of re-dried leaves of exhausted tea. The Chinese, as usual, are not behind us in rascality in this matter. The practice of sending spurious tea to this country is largely on the increase. It is time that adulterators should be severely punished as in France.

First Report of the Medical Committee of the Charity Organisation Society, with Rules for Provident Dispensaries, adopted by the Council, October 30, 1871. London, Lewis, 1871. This is a most excellent pamphlet and should be in the hands of all reformers. It appears that the 16 general hospitals of London saw 541,775 out-patients in 1870. It is the out-patient department of hospitals that is most abused. There are 80 free hospitals and dispensaries in London at present. The committee think that the applicants to an hospital might easily be discriminated by some agency such as the Charity Organisation. There are only a dozen provident dispensaries in London; whilst in Derby, Coventry and Northampton there is one to every 40,000 inhabitants. Benefit clubs only admit men, and many have no Medical man attached to them. The committee recommend 1.—That the Provident principle be greatly extended. 2.—That hospitals should be reminded by the Charity Association of its power of weeding out cases. 3.—That Provident Dispensaries should be affiliated to hospitals in each district (as at Devonport). 4.—That the Free Dispensaries should be changed into Provident ones. 5—That in new districts a Provident Dispensary should be erected. We wish all good to this excellent association. May it flourish!

How to prevent Small-pox, by MORDLEY DOUGLAS, M.R.C.S. Baillière, Tindall and Cox, 1871; third edition. The author of this pamphlet says truly in his preface, "The evidence in favour of vaccination is so great as to gain the assent (with a few unimportant exceptions) of the whole Medical Profession, so great that a high authority, Professor Alison, has declared, "he who disputes it is equally unreasonable as he who opposes any proposition in Euclid." Mr. Douglas mentions that 188 cases of small-pox had been under his care during the late epidemic; of 164 vaccinated only four died (all badly vaccinated); whilst of 24 unvaccinated, 14 died. This is a very valuable pamphlet.

◆

Medical News.

Royal College of Physicians of London.—At the ordinary quarterly meeting of the College on the 25th inst., the following gentlemen having passed the required examinations, were admitted Members:—

Berkart, Isidor B., M.D. Wurtzburg, Harley street.
Vanderstraaten, Julian Louis, M.D. St. And., Civ. Med. Serv. Ceylon.
Ralfe, Charles Henry, M.B. Cambridge, Queen Anne street.

Royal College of Surgeons of England.—The following gentlemen, having passed the required examinations for the diploma, were duly admitted Members of the College at meetings of the Court of Examiners on the 23rd and 24th insts.:

Barton, James Edward, Brompton.
Bower, Augustus Edward, L.S.A., Nantwich, Cheshire.
Brittin, Frederick G.M., L.S.A., Wansford, Northampton.
Buchanan, Arthur, Gloucester.
Chambers, Eber, Ryde, Isle of Wight.
Corric, Alfred Thomas, L.S.A., Plymouth.
Deeping, George Davidson, L.R C.P. Lond., Newark-on-Trent.
Dempsey, Meldon Joseph, L.S.A., Charterhouse square.
Dobie, Stanley Locker, Carlisle.
Dunstan, Lobert, L.S.A., Liskeard, Cornwall.
Edwards, John Ellis, L.S.A., Aberdare, South Wales.
Ferris, John E. C., L.S.A., Bayswater.
Garrett, John, Salisbury.
Godfray, Amiraux, Jersey.
Hues, James John, Handsworth, Staffordshire.
Jackson, George E. C., North Reston, Lincolnshire.
Johnstone, John Lawson, Liverpool.
Jones, Lewis Herbert, Ruthin, Denbighshire.

Kelly, Michael James, Baltinglass, Co. Wicklow.
Langdale, Henry Marmaduke, L.S.A., East Hoathley, Sussex.
Llewellin, George Joseph, L.S.A., Haverfordwest.
Marsh, Walter Alfred, L.S.A., Newington.
Moseley, William Arthur, L.R.C.P.Edin., Nassau, Bahamas.
Pigeon, Henry, L.R.C.P.Edin., Redland, near Bristol.
Pike, William Royston, L.S.A., Leicester.
Procter, Thomas, Wigan, Lancashire.
Pugh, Edgar Joseph, L.S.A., Waltham Abbey.
Rae, William, King's Lynn.
Rix, Benjamin, L.S.A., East Meon, Hants.
Rosten, William Martin, Walsall, Staffordshire.
Salmon, Alfred Lidgey, L.S.A., Truro, Cornwall.
Sarjant, Josiah John, L.S.A., Isle of Dogs.
Shearman, William Millar, Gateshead.
Steele, Russell, L.R.C.P.Edin., Reigate, Surrey.
Sylvester, Kirwan Francis, L.R.C.P.Edin., Trowbridge, Wilts.
Taylor, Herbert, Kennington.
Thornton, Philip, L.S.A., Norwood.
Tudge, James M'Dougall, L.S.A., Hereford.
Underhill, Charles Edward, M.B.Cantab., Tipton, Staffordshire.
Wallis, Edward Darby, L.S.A., Bodmin, Cornwall.
Woodward, George, Bicester, Oxon.

Society for Relief of Widows and Orphans of Medical Men.—The Directors of the above society recently held their usual Quarterly Court at the rooms of the society in London, the President, Dr. Burrows, being in the Chair. Fresh applications for grants were made by 3 widows and 4 children. The case of 1 widow was postponed for further information respecting her income. The sum of £1,249 was distributed amongst the 55 widows and 43 children now recipients of assistance from the funds of the society. The death of 1 widow was announced, and the grant to another was no longer required. Several children had become ineligible for grants during the last half year, 2 having been elected scholars at the Medical Benevolent College, Epsom, and the grants to others ceasing on account of age. Six candidates for membership were proposed to be elected at the next Court.

The case of Christiana Edmunds.—Mr. Baron Martin, who left the case in such an extraordinary fashion to the jury, who made the very unjustifiable remark that persons of position were commonly excused on the ground of insanity, and who expressed his approval of the verdict of the jury in such terms as to lead to the impression that he believed the prisoner to be perfectly sane, has since written to the Home Secretary, recommending that the state of mind of Christiana Edmunds should be inquired into. Accordingly, two physicians, not in the least degree better qualified to form an opinion than those who appeared on the trial, and one apparently selected on the score of his temporary popularity for success in a case not in the remotest degree connected with mental disease, have been charged to examine the prisoner, and have pronounced her insane. Mr. Baron Martin must surely hold that a jury is not a tribunal before which the question of sanity or insanity should be tried, and in this we entirely agree with him.—*Globe.*

War-office, Jan. 20.—The Queen has been graciously pleased to give orders for the appointment of Sir William Jenner, Bart., M.D., one of the Physicians in Ordinary to Her Majesty, to be an Ordinary Member of the Civil Division of the Second Class, or Knights Commanders of the Most Honourable Order of the Bath.

Whitehall, Jan. 20.—The Queen has been pleased to direct Letters Patent to be passed under the Great Seal granting the dignity of a Baronet of the United Kingdom of Great Britain and Ireland unto William Withey Gull, of Brook street, in the parish of St. George, Hanover square, in the county of Middlesex, M.D., and the heirs male of his body lawfully begotten.

The poisoning of a Workhouse-Surgeon in Manchester.—At the Manchester City Police-court yesterday Hannah Steele was brought up on remand, charged with poisoning Mr. Andrew Harris, late-house surgeon at the Manchester Workhouse. Professor Grace Calvert gave evidence as to the analysis of the stomach and intestines of deceased, and said that he had found evidences of atropine poisoning in the blood of the heart. He had also found atropine in the stomach. He found no atropine in the tea or milk. Emily Brandon, wife of the master of the Manchester Workhouse, said when the prisoner heard that the deceased had been poisoned she became very excited and said, "Send to the infirmary for a battery." The magistrates, after a short consultation, said they had resolved to commit the prisoner for trial. The prisoner, on being asked if she had anything to say, said, "I never did it; I did not do it; and I did not know anything at all about it until my husband came and told me."

Comparative deadliness of weapons of war.—The *Elberfield Gazette* publishes some curious statistics of the comparative deadliness of the different weapons used in the Franco-German war. According to them, of 3,453 Germans wounded before Metz, no fewer than 95·5 per cent. were struck by Chassepot balls; 2·7 per cent. only were wounded by projectiles from heavy guns, and there were only 0·8 per cent. of wounds from cold steel. As to the French wounded, it is calculated that as high a proportion as 25 per cent. were wounded by artillery projectiles, and about 70 per cent. by the fire of the *zundnädelgewehr.* No fewer than 25,000 Frenchmen in all were struck by the projectiles of the German artillery. This gives an average of one effective shot in every three fired from the German batteries—a result which appears to us to be hardly credible.

ROYAL COLLEGE OF SURGEONS IN IRELAND.

At the Quarterly Examination held on the 9th, 10th, and 11th insts., the following gentlemen passed the first-half of their Examination for the Letters Testimonials, viz.:—

Benjamin Armstrong; Francis T. Bray; Valentine E. Brown; Henry W. Burton; James H. Callery; Charles J. Diamond; Thomas Elliott; William H. Elliott; John K. Gentleman; Mathew P. Healy; Henry J. Hillis; Richard Jackman; Thomas J. Kelly; Robert Margill; Michael J. Malone; Roger MacAuby; James McGann; Archibald McKinlay; James Murtagh, Hamilton Macmillan; John L. O'Keefe; Thomas O'Meard: Edward Poole; Samuel B. Shekelton; Charles J. Smith; William J. Smyly; Henry J. Tweedy; William M. Whittaker; John H. Williams; and Stewart Woodhouse.

At the Examinations in General Education held on the 17th inst., the following gentlemen were awarded Certificates of Qualification. The names in the first and second classes are in order of merit:—

First Class.—Michael Molohan and James J. Hogan.

Second Class.—William J. Cahill; Peter J. Hughes; James J. O'Brian; Frederick Walsh; Michael W. Korin; William Thompson; Henry Howard; Edward Walshe; and Patrick Carney.

Unclassed.—Charles Anderson; Thomas Bellew; Ulick J. Bourke; Edward D. Foley; Robert Grier; John Keogan; Hugh Mackintosh; Patrick M. Poett; Henry N. Powell; Samuel T. Reed; William Ross; Kennedy Ryan; John J. Smith; Bernard J. Smith; Terence Smith; and Lawrence T. Ward.

At the Quarterly Examination held on the 23rd, 24th, and 25th insts.; the following gentlemen passed their first, second, third and final examinations for the Letters Testimonial, and were admitted Licentiates of the College, viz.:—

Nicholas E. Atkin; Robert Baxter; Valentine E. Brown; Arthur C. Clarke; Christopher Elliott; Thomas Elliott; William H. Elliott; Francis E. Flood; Thomas H. L. Heath; Henry J. Hillis; John A. Irvine; Thomas J. Kelly; William L. Micheiy; Hamilton Macmillan; Robert Magill; Charles W. Magrane Myles; O. C. McSwiny; Lyster A. Nolan; Frederick A. Pope; John W. Searry; William J. Smyly; Henry J. Tweedy; William M. Whittaker and Stewart Woodhouse.

THE SMALL-POX IN DUBLIN.

At the last meeting of the Medical Society of the College of Physician, Dr. Grimshaw communicated some very interesting statistics of the progress of the present small-pox epidemic in Dublin. The Cork street Fever Hospital had received altogether 261 cases, out of which 56 had died, being a proportion of 25·1 per cent. of the cases which had been treated to a termination of these 261 cases; 202 had been vaccinated, and 57 had not. Of the 202 vaccinated cases, 19 died, being 9·4 per cent., while of the 56 unvaccinated, 34 died, or 60·77 per cent. of the whole.

Into Dr. Stevens's Hospital, 28 cases had been admitted, of which 2 had died, 1 being unvaccinated. Taking the total of the cases treated in both institutions, 58 deaths had occurred in 289 cases, or 20 per cent. Of these, 229 had been vaccinated, amongst whom 20 had died, or 8·7 per cent.

Of the first 15 cases admitted into Cork street Hospital, eight had taken the infection directly from England, and from Guinness's Brewery, 12 persons had been admitted, the disease had been contracted from a workman who had come from England, and been employed in the co-operage.

Dr. Grimshaw forcibly illustrated the means by which the disease was propagated, by a statement that one of his patients had been working as a tailor in a crowded workshop, another had been dressing hair, a third cutting up meat as a butcher, and a fourth selling groceries while in an advanced stage of the disease.

Of the 300 cases which were admitted to the two hospitals not one had been revaccinated.

TONED *versus* WHITE PAPER.

In improving the quality of the paper, and giving it the tint which is generally considered most pleasant for reading purposes, we expected to receive the concurrence of all our friends, and were hardly prepared for the following, which we cannot resist giving publicity :—

To the Editor of " The Medical Press and Circular."

Dear Sir,—I should be very pleased could I take your Medical Press and Circular in ; but its being printed on TINTED paper deprives me of the pleasure of reading it. As we advance in life the convexity of vision becomes less and less, and it requires the greatest possible contrast of *black* and *white* to afford old age the facility of reading. It was a sad mistake Her Majesty publishing her works on *toned* paper. Fashion in publishing most books has provoked this same coloured paper, hence many are prevented from reading. Such is my case, and I know many others. I got your number of January 17th, read to me by chance, I was very much pleased with, and regret not being able for the reasons given, to read it myself.

I am, &c.,
J. C. H———.

With all due deference to our Correspondent, we certainly do not think the Retinal Image would be less distinct in the use of *toned* paper, because the contrast is really not less than is the case with *white* paper, while the irritation from too much reflexion of light would be less troublesome. From the many complimentary letters we have received we feel highly gratified with the change we have made in our new volume, but thank our correspondent nevertheless for his courteous letter.—(Ed. M. P. & C.)

APPOINTMENTS.

Archer, E. G., M.R.C.S., Resident Medical Officer to the Jersey Infirmary.

Brett, Dr. A. T., Medical Officer to the London Orphan Asylum.

Campbell, R. L., M.D., Medical Officer of Health for Stourbridge.

Hart, E. J., M.R.C.S., Surgeon to the Brighton Dispensary.

Haynes, S., M.D., M.R.C.S.E., Surgeon-Accoucheur to the Malvern Lying-in and Samaritan Charity.

Holland, J., F.R.C.S.E., Medical Superintendent of the Lancashire Lunatic Asylum, Whittingham, near Preston.

Ley, H. R., M.R.C.S.E., Medical Superintendent of the Lancashire Lunatic Asylum, Prestwich.

Moon, D. S., L.R.C.P.Ed., L.R.C.S.Ed., Surgeon to the East Dispensary District of the Royal Infirmary, Dundee.

Phelps, F. P., M.R.C.S., Surgeon to the Exeter Lying-in Charity.

◆

Marriages.

Webb—Waters.—On the 23rd inst., at St. Paul's, Newton Abbot, G. Fortescue Webb, Esq., F.R.C.S.E., of Exeter, to Georgina Marion, daughter of George Waters, Esq., F.R.A.S., late of the Madras Civil Service.

◆

Deaths.

Clayton.—On the 23rd ult., M. H. Clayton, M.R.C.S.E., of Calthorpe road, Edgbaston, aged 46.

Fergusson.—On the 19th ult., John Fergusson, Surgeon, of Barrow.

Procter.—On the 18th inst., at Marsh, Wistanstow, Thomas Benjamin Procter, M.D., aged 71.

PUBLIC SCHOOL EDUCATION IN IRELAND.
COLLEGE OF ST. COLUMBA, COUNTY DUBLIN.

Visitor : THE LORD PRIMATE.

The College is intended for the Education of the Sons of the Nobility, Clergy, and Gentry, from the age of nine years and upwards. The course of instruction is similar to that of the great Public Schools in England, in which Classical Studies are made the chief foundation. Particular attention is also paid to Mathematics and English. French, German, Drawing, and Vocal Music are also included.

Boys are prepared for the Universities of Dublin, Oxford, and Cambridge ; and to a considerable extent for the Military and Civil Service.

Terms—*Sixty Guineas*, inclusive.

There are Two Exhibitions attached to the School, tenable in the University of Dublin, worth £20 to £30 a year.

Applications should be made to the Rev. the Warden.

The Christmas Vacation ends on January 25th.

COOKESTOWN HOUSE, INSTITUTED FOR
THE MEDICAL TREATMENT OF THE INSANE OF BOTH SEXES.

This highly respectable Mansion in no respect resembles, either internally or externally, what is usually known as an Asylum.

The Demesne, Conservatories, Graperies, and Grounds are unusually extensive, and in good condition.

There are Billiard Tables for both sexes, with indoor and outdoor amusements, including Vehicles.

Cookestown House is within three miles of Carrick-on-Suir Station, with a like distance from Fiddow, both on the Waterford and Limerick Lines, and in connection with the G. S. & W. and Kilkenny Lines.

For terms, and Form of Admission, apply to the Resident Physician.

JOHN PEPPARD, M.D., &c.
Cokestown House, Piltown, co. Kilkenny.

The Medical Press and Circular
OFFERS UNUSUAL ADVANTAGES

FOR the Insertion of announcements, from its extensive and largely increasing circulation in each of the three divisions of the United Kingdom and the Colonies. Being also supplied to the Hospital Libraries, &c., it will be found a most valuable medium for Advertisements of Books, Vacancies and Appointments, Sales and Transfers of Practices, Surgical Instruments, Chemicals, and Trades generally.

CLINICAL NOTES AND OBSERVATIONS.

By Henry Lee,

Surgeon to St. George's Hospital.

III.—Secondary Mortification from Disease of the Arteries.

When the morbid deposit is firmly adherent to the coat of the vessel, a deposit of discolorised fibrin from the blood will take place, which will temporarily unite the torn edges of the divided membrane and cover the exposed surface of the deposit. This layer of fibrin thus forms a bed in which subsequent changes occur. But if the morbid deposit in the artery has undergone any great degree of softening at the time the internal coat gives way, then its more fluid parts become necessarily mingled with the blood and carried to a greater or less distance in the course of the circulation. The same effects will then be produced, whether these morbid deposits be poured into the circulation as now described, whether similar morbid matters be generated in the blood itself, or whether they be brought from some distant part of the vascular system. There is this important fact, however to be noticed, that when any morbid matter is generated in an artery it will expend its first and principal influence upon the parts to which that artery is distributed, and the remainder of the system may, or may not then be affected.

Disease of the arteries has very generally been considered as a cause of mortification, and the diseased conditions, have by most authors (as in cases related in Communication No. II.) been attributed to inflammation of the arterial coats.

Earthy concretions, again, in the arteries of the lower extremities, since first noticed by Cowper and Naish, have been regarded as the cause of the closure of the internal canals, and of the consequent mortification of the extremities. "But," as is observed by Mr. Hodgson "our knowledge of the power of the collateral circulation in every part of the body, will not allow us to admit the obliteration of the trunks as a sufficient cause of mortification from deficient supply of blood." Some other cause of this kind of mortification had then to be sought, and a sufficient one was thought by some writers to have been found in the theory that if the large arteries were diseased the small ones would be so also, while others have supposed that the want of elasticity and organic power would interfere with the due supply of blood in a degree sufficient to account for the effects observed in gangrene. Both these suppositions are entirely devoid of proof, for although in cases of dry gangrene the arteries are often found to contain bony deposits and the smaller arteries are also sometimes found diseased, yet are these deposits never found in those situations in which the gangrene actually takes place; for instance, in the pulpy vascular extremities of the toes, in the lips, cheeks, or lobes of the ears. The smallest spiculæ of bone might be detected by the delicate sense of touch in any of these situations, yet in the arteries of the size here found is there never any bony deposit detected. Again, gangrene is often found where no disease of the arteries can be recognised, as shown by the following cases:—

J. F. L., a boy, æt. 6, apparently in previous good health, suddenly fell down without any complaint on the 23rd of July, 1855. His limbs were found quite relaxed, and after a short time he said it was so dark that he could not see, when taken home he spoke little and incoherently, but his limbs were stiff and cold; in the evening he revived, became warm, and slept. During the night he complained of pain in the left foot and great toe, the latter was found to be black at the tip, towards morning he complained of pain in the thigh and leg of the same side; on the 24th a cord of the thickness of the finger was felt from Poupart's ligament downwards in the direction of the vessels, about one-and-a-half inches long. This cord is tender on pressure and the skin over it is somewhat red coloured, a black gangrenous vesicle, as large as a bean in a half moon shape presented itself under the nail, the toe and that next to it, were swollen, and there was considerable œdema up the instep, motion in the left leg is attended with pain, over the aorta a "doubling" was heard of both sounds of the heart; these sounds were propagated into the vessels of the neck, there was here also a strong nervous murmur.

July 25th.—The upper part of the thigh was œdematous.

28th.—The œdema of the instep had discharged.

August 1st.—The œdema of the groin was gone, but large vibices occupied its situation on the thigh.

8th.—The sore on the great toe was rapidly healing.

24th.—The patient was dismissed, the sore on the toe was nearly healed, the reduplication of the sounds of the heart continued.—Professor Gustaf Von Düben.

Wm. R., a middle-aged man, had suffered from stricture for many years, but otherwise had good health; after having for some time neglected the stricture, he had an instrument introduced upon the 24th of June, 1856. A difficulty occurred in the passage of the instrument, some blood followed, and the water was not drawn off. A severe rigor followed, and he felt very unwell; on the following day he had what he termed a kind of erysipelas, confined to the skin of the mouth, and the right ear, this terminated in the formation of dark black scabs in patches, then peeled off. Both nostrils became stopped with black matter. There was hiccough, and a continued uneasy sensation at the pit of the stomach.

On the 11th of July there were still darkish yellow scabs on the ear and lip, and great general debility, after this he slowly regained his strength.

A woman, æt. 27, died of endocarditis (so called), on the 10th of January, 1856. The mitral valve was covered with brittle masses, which under the microscope, were seen to consist of dense, amorphous, highly granular, yellowish looking lumps. Portions of fibrinous concretion (emboli) were found in the fine branches of the coronary artery of the heart. These could be recognised by the naked eye, and had produced an acute yellow softening of the muscular structure: numerous hemorrhagic knots were found in the spleen in which the endocardic emboli could, with great constancy, be traced into the penicilli. These emboli were also found to fill some of the little arteries of the kidneys.—Virchow.

These cases demonstrate the fact that mortification may be produced by the condition of the blood, alone, independently of any disease of the artery.

Again M. Cruveilhier has shown (*Anatomie Pathologique*, vol. II., p. 301), hat an artery which supplies a limb may be obstructed for a considerable distance without any mortification following; but that if an irritating injection be thrown into such an artery, mortification will immediately follow. It is remarkable, also, that mortification seldom attacks those structures which have a scanty supply of arterial blood, but that it almost invariably shows itself first in those parts which have the largest supply of blood-vessels; the vascular cheeks and lips in children, the vascular extremities of the toes in those of advanced age, are parts very frequently affected. If a simple deficient supply of blood were the cause of mortification, in such cases we should expect to find it first developing itself in the tendons and ligaments, and we should expect to find that the cellular tissue would perish always before the skin. The reverse of all this often occurs. The parts in which mortification in general shows itself have in truth a wonderful power of sustaining their life with a very small supply of arterial blood, and even as demonstrated in Communication No. I., when separated from the body.

In a case formerly under the author's care a flap of skin was taken from the side of the chest and placed across the neck in the centre of the cicatrix of a burn. It appeared to unite favourably in its new position, when the patient suddenly got into very bad health, the old cicatrix ulcerated and left the portion of the skin newly introduced, and attached by a small base, peninsulated. This portion of skin, however, remained unaffected by the ulceration, and ultimately again reunited to the skin of the old cicatrix. In such cases the arterial impulse through the transplanted portions of skin must be very slight, and in the face of such well-known facts the want of arterial impulse can hardly be seriously maintained as a sufficient cause of itself for mortification.

◆

NOTES ON PHTHISIS PULMONALIS, &c.

By R. Locke Johnson,

Visiting Physician to the Infirmary for Consumption and Diseases of the Chest, Margaret Street, Cavendish Square, W.

Louisa W., æt. 29, single, was a domestic servant. Has been ill two years or more. Admitted to University College Hospital, Feb. 19, 1866; discharged and went to Home for Incurables. After this took a situation, but got worse and went into the Middlesex Hospital; whence, being discharged was admitted to North London Consumption Hospital, May 14, 1868. Suffering from very great dyspnœa, expectoration of purulent character, constant cough, debility, &c., aggravated by movement; one leg (the left) seems heavy, often loses sensation in it; no fever; complains most of want of breath, and stuffiness of the chest; respiration 30 to 40; pulse only 80, steady; appetite good; asks for stimulants; bowels open twice daily, and somewhat liquid; moist *râles* throughout both lungs.

Tr. Camph. co., & Vin ipeca., ♏xx. *ter die.*

May 23.—Cough and expectoration not at all relieved; worse in the mornings; nurse says spits a whole mug-full daily (1 pint); no fever nor hectic; breath very short and difficult, varies from 30 to 40; pulse 80, fair, but sometimes (as on exertion this afternoon) becomes suddenly imperceptible. Auscultation obscured all over by loud cooing and moist *râles* which occupy the whole space of the thorax front and back; heart sounds very weak and distant, with now and then a tumultuous interruption. There is also dulness on percussion over sternum, apparently caused by encroachment of liver as dulness extends in that direction.

May 28.—Continues much the same; the moist breathing all over remains; the cough very troublesome; expectoration continues; excessively nervous; on attention being directed to breathing dyspnœa recurs, to heart palpitation comes on; listening when she is not aware of it both sounds of heart heard but very weak; attempt to move aggravates dyspnœa and brings on palpitation.

Zinci, val. gr. ss., ter. die., in pills.

June 1.—Better; expectoration less.

June 12.—Has made some progress; feels stronger; has been able to move more; the expectoration is less copious, not more than half-a-pint daily; more frothy; very purulent; cannot take any more of the pills.

℞ Pulv. dov., gr. v.;
Pot. nit., gr. x., h. s. s.;

℞ Tr. camph., co. ʒss.;
Quinia dis., gr. j.;
Acid sul., dil., ♏x.;
Aq., ℥., bis.

June 15.—Has improved a little and walked across the ward several times, but the dyspnœa is excessive; the heart sonnds both heard but very feeble; she is impatient of auscultation and declares the pressure of stethescope, however gentle, gives pain. Her pulse is feeble, but regular, 90; respiration about 40; embarrassed all over the chest; large rhonchi are heard as before; the percussion note clear throughout.

℞ Pulv. dov., gr. v.;
Pot. nit, Pot. bic. aa. gr. v. o. n.;
Rept. mist, quin.

June 20.—Has been improving gradually.

This patient left the hospital a fortnight later, as she felt well enough to go out and do something.

Timothy C. was admitted as a case of "consumption" on Jan. 31st, and on examination it was manifest there was dulness under right clavicle, with prolonged expiration and bronchial breathing, but no rhoncus; muco-crepitant *râles* at both bases; some linctus was ordered as he complained of cough.

Feb. 2.—He complained of pain in the chest and occasional palpitation. On stripping to auscult noticed the ziphoid cartilage much depressed (at level of ziphoid cart. 34 inches) two sides equal. The apex beat is seen distinctly under the ziphoid in the centre of the epigastric angle and felt distinctly; underneath the left nipple is a considerable depression in the heart's place, and in that the respiratory murmur is heard, and it is clear on percussion. Three inches below nipple is a little dulness, as if cardiac; and this extends in a horizontal line across the epigastrium and is lost in the hepatic dulness; seems about one-and-a-half inches deep. Apex sound of heart most distinct where seen beating; base sound heard most between junction of 5th and 6th ribs with sternum; no murmur detected; pulse 80, rather weak.

Tinc. camph. comp., ♏xx.;
Sp. chloroform, ♏xx.;
Inf. cascarilla, ℥. t.;
Ol. morrh.

This patient improved very much so far as pulmonary symptoms go, indeed, he got—as he said—almost well; but still had occasional pains in the chest and palpitation.

He left by his own wish.

Thomas B., æt. 22, single, lawyer's clerk, admitted June 2nd, with a cough of eighteen months' standing, which began with a slight hæmoptysis, and never had any other disease except a fever ten years ago. Has lost his mother and two brothers in consumption. He now has cough, cannot sleep at night for the feverishness, which ends towards morning in heavy sweats; suffers a good deal from palpitation; pulse feeble; lost flesh rapidly the last two months; no appetite; tongue furred; bowels regular. In left subscapular region there is a flattening over, while the voice sound is loud. There is also wheezing at the close of each inspiration. On the right side there is prolonged expiration.

Tr. camph. co., ♏xx.;
A. nit. dil, ♏xx.;
Inf. gent. co., ℥j. *ter die.*

June 15.—Appetite better; bowels regular; cough less; not much now; physical signs same.

Rept. mist., Ol. morr., ʒij. *bis. die.*

June 21.—Appetite improved; tongue cleaner; bowels regular; cough better.

S. J., æt. 30, a widow, with one child, looks anæmic, has been an out-patient several weeks, taking mostly cough medicines and tonics with cod liver oil. She complains of cough, worse night and morning, with yellow expectoration, frothy phlegm, and retching. Has been ill between six and seven years. Is much thinner than a few years ago, but has not lost flesh, she thinks, during the last six months. Has pains in chest and shoulders at intervals; frequent attacks of palpitation and "spasms." Any exertion brings on this, violent coughing is the worst symptom of all. On inspection, the heart's impulse over the left side of the chest is diffused. On palpation there is a distinct thrill, a loud murmur extending over the whole base, and carried upwards along the subclavian. There is also a very loud murmur in the axilla. The patient remained in the hospital two months, during which she greatly improved. The cough subsided; the attacks of palpitation became less severe and less frequent; she increased in weight, and her appetite returned. She took most of the tonics; cod liver oil and various anodynes, cough mixtures were tried during the first part of her stay.

A SIMPLER MODE IN DIVISION OF THE FRÆNUM LINGUÆ.

By R. Hanslip Sers, M.R..C.S.

In division of the frænum linguæ, text books direct us to use a blunt-pointed pair of scissors, to direct their points downwards, to keep as close to the lower jaw as possible, and to avoid the lingual artery. In what might well be made a riskless performance, we are exhorted to provide a special instrument, and to observe a somewhat formidable array of precautions. Any one who has frequently relieved tongue-tied-infants after the customary manner, must be aware of the necessity to apply sharp scissors, otherwise the mucous membrane from its elasticity resists complete division. Simple operations are not invariably performed with ease. An infant may render our manœuvres awkward much to the dismay of the mother and the chagrin of the surgeon. To obviate this difficulty, I can recommend the following practice:—Direct the infant's face towards the light, pass the left index finger along the floor of the mouth (the lower jaw is kept open by being made its fulcrum), along the left side of the frænum linguæ until the latter is fairly put on stretch, so as to make palpable the necessary extent of incision, place the sharp-pointed blade of an ordinary pair of scissors horizontally across the right angle of the mouth, in a line with the apex of the engaged finger, push its point through the membrane on to the tip of the finger, bring the blunt blade hitherto outside the mouth into contact with its fellow, and withdraw them directly forwards protected by the aforementioned finger, and this minor operation is completed.

◆

Hospital Reports.

ST. GEORGE'S HOSPITAL.

Inflammation of the Base of the Tongue.

(Under the care of Dr. John W. Ogle.)

The patient was a man, æt. 22, who on the day before admission, suddenly became affected with what he called "sore throat" and a pricking sensation in the fauces. This became worse in the course of the day, and he passed a painful restless night. The breathing, however, was not affected, and there was no cough. When admitted he had much pain on both sides of the throat, and great difficulty and pain in swallowing. The tongue which was coated was very œdematous, and he had difficulty in opening the mouth wide. Nothing wrong was found on examining the fauces, excepting slight enlargement of the tonsils. The voice was not affected; the pulse 100, and feeble, and the hands and feet cold; the expression was anxious. It appeared that five months previously he had had a similar, though less severe attack. Leeches were applied to the throat, and mineral acid with chlorate of potash and bark given, and he inhaled the steam of vinegar and water. On the day after admission, he was with difficulty purged by calomel and senna. For three or four days he was in great pain, not only about the throat, but also in the ears, which was much relieved by poultices, and the nights were very painful. No affection of the larynx came on, nor did the tongue swell to any great extent. Improvement came on about the 9th day, and seven days after admission he was "quite relieved;" he left the hospital well about fourteen days after admission.

Hæmaturia—Calculus in Kidney?

The patient, Louisa B. æt. 27, had been suffering for eight days with pain at the bottom of the back which was at first attended by "cold shivering," and which had so increased as to become most agonising, and had extended round the loin on the right side and down in front towards the groin. On the day before admission, so much blood had passed mixed with urine, that it was thought to be entirely blood. As soon as admitted, being in excruciating pain, she was placed in a hot bath, and a grain of opium with three of calomel were given, followed by castor oil in four hours. The bladder was emptied by a catheter, and the urine was drawn off mixed with a very large amount of blood of a bright red colour. Great relief followed the use of the bath, and on the next day scarcely any pain existed. As the bowels were not opened by the oil a purgative enema was given, and at the same time gallic acid in 15 grain doses were given thrice a day. There was no return of pain, and the urine which was passed abundantly day by day became freer from blood. At no time was anything wrong found on examination of the urine microscopically or otherwise, and Dr. Ogle supposed that the hæmorrhage must have arisen from the presence of a calculus in the right kidney.

Transactions of Societies.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

TUESDAY, JAN. 23RD, 1872.

J. A. BOSTOCK, C.B., Vice-President, in the Chair.

ON THE EXCITABILITY OF DIFFERENT PARTS OF THE TRUNK OF A SPINAL NERVE WITH A "SCHEMA OF THE CIRCULATION."

BY WILLIAM RUTHERFORD, M.D., F.R.S.E.,

Professor of Physiology at King's College, London.

IN this communication Professor Pflüger's experiments regarding the excitability of different part of the trunks of the motor fibres of spinal nerves are described, and his "avalanche hypothesis" founded thereon criticised. The faulty character of his experiments is pointed out, and those performed by the author are narrated. The latter conclusively show that Pflüger's explanation of his experiments is untenable; that the avalanche hypothesis regarding the transmission of nerve force has no fact in its support; and that the excitability of both the *afferent* and *efferent* fibres of a spinal nerve is inversely as the distance from the spinal cord. The possible explanations of this singular and novel fact are considered, and the bearing of this discovery upon our ideas regarding the nature of the influence which travels along a nerve is indicated.

MR. HENRY POWER always considered Pflüger's hypothesis fraught with difficulty—that force should gain by being expended. Did Dr. Rutherford think the increased excitability due to the thinness of the coats of the medullated fibres near the spinal cord?

DR. RUTHERFORD was glad of the suggestion; meantime, he had not made up his mind.

DR. RADCLIFFE was glad to hear a refutation of Pflüger's views. Did not the fact that nerves die centripetally explain something?

DR. RUTHERFORD sometimes cut the nerve at the distant electrodes, when the cutting for a time caused the excitability to increase, so as almost to equal that of the other and cerebral end.

MR. POWER asked if Dr. Rutherford had seen Schiff's experiments, which went to show that the excitability of the pneumogastric was greatest near the brain?

DR. RUTHERFORD had done so. They confirmed his view.

PROPOSED FORMS OF SURGICAL RETURNS AND REPORTS TO BE USED IN WAR.

BY DEPUTY INSPECTOR-GENERAL C. A. GORDON, M.D., C.B.

(*Communicated by* BERKELEY HILL, F.R.C.S.)

The object of the proposed forms is to present information regarding wounds received in battle and operations performed in their treatment in a manner calculated to facilitate comparison regarding their severity, results, prevalence, and fatality of complications usually met with, and also to arrange observations upon subjects of surgical interest in a definite manner.

Table No. 1.—In this form wounds are arranged (*a*) according to their position, (*b*) according to severity, and (*c*) the deep parts of importance implicated. The different columns into which the form is divided indicate the circumstance under which wounded have been admitted, the several conditions in which they are discharged, and, in regard to those who die, the causes of death, distinguishing particularly the cases of mortality by *hospital* diseases and complications.

Table 2.—This form is intended to contain a record of the various operations performed. The operations are arranged according to their kind, as—(*a*) amputations, (*b*) excisions, (*c*) resections, (*d*) ligatures, (*e*) trephining, (*f*) extractions, (*g*) other operations. The first four classes are severally arranged according to region or part of the body, and in regard to each case the return will show the manner in which it was admitted, period of operation, the circumstances under which the patient is discharged, and in cases of death, the precise cause, as far as practicable, of the fatal termination.

Form 3, or Report. This presents different "headings" under which information may be arranged for the purpose of being subsequently collected and condensed. These headings include the following points—viz., (1) those referring to form 1; (2) those referring to form 2; (3) conditions of individual hospitals; (4) as to certain diseases that may appear among the wounded; (5) as to the important question of hæmorrhage; (6) as to the relative success of primary and secondary operations; (7) as to other surgical points of interest, some of which are enumerated; (8) as to the character of wounds by new projectiles and other arms; and (9) such other general subjects as are not included under any other of the above heads.

The CHAIRMAN thought that, as an army surgeon, he ought to tender his thanks to Dr. Gordon.

MR. WYATT said that the more succinct the forms of notes to be taken in actual campaign, the more likely were they to be accurate. One would hardly be able to note all the points suggested by Dr. Gordon under such circumstances. He had drawn up a form which was approved of in the operations at Paris. It was important to have a form which would be available for use afterwards. In all the civil hospitals of Paris one definite form was used. It would be well could we have a similar one adopted in London.

DR. CHARLES MAYO agreed with Mr. Wyatt as to the difficulties in the way of filling up these forms. Field statistics were very uncertain, especially when the army was constantly moving on. Then it would be impossible to fill them up, however desirable to do so.

DR. RUTHERFORD next demonstrated the uses of a New Schema of the Circulation, and the meeting adjourned.

Placental Expression.

DR. T. PARVIN in an interesting article on placental extraction and expression, gives an elaborate review of all the authorities on the treatment of the third stage of labour. He has adopted and strongly recommends the method of Prof. Crédé, of Leipsic. It is thus described: "Crédé's method is simple in principle and easy execution. Its object being to reinforce the uterine contractions, the accoucheur should act during a pain and not in the interval. Success is the more rapid the sooner after the expulsion of the fœtus this effort is made. Nevertheless, it may succeed a quarter or even half-an-hour after, but this presents an unfavourable condition when the retraction of the uterus has attained its maximum in the first contraction which normally occurs after the escape of the infant; embrace the fundus and the superior part of the anterior wall of the uterus with the entire hand placed transversely, then press downward and backward, assisting, if necessary, with the left hand. Under this pressure, the placenta and membranes are detached; then engage in the uterine orifice; sometimes even escape from the vagina suddenly just as a cherry seed escapes when the cherry is pressed between the thumb and finger." The advantages claimed for this practice are 1st, air cannot enter the uterus; 2nd, hæmorrhage and retention of the placenta are prevented; 3rd, uterine inversion and hour-glass contraction will be more securely guarded against; 4th, the time required to complete the last stage of labour is greatly shortened, three to thirty minutes being all that is needed.

WEDNESDAY, FEBRUARY 7, 1872.

GOVERNMENT INJUSTICE TO THE PROFESSION.

M. DECAISNE has translated into French the account of the Siege of Paris read at the Plymouth meeting of the Medical Association, by Deputy Inspector-General Dr. Gordon, C.B., who was sent by the British Government to report. The translation has appeared in the *Revue Scientifique*, and has since been issued as a pamphlet by the publishers to the Paris Academy, MM. J. B. Baillière et fils.

This appreciation of the value of Dr. Gordon's work reminds us that his own government has not yet promoted him or conferred any honour upon him,—an instance of that unaccountable neglect of deserving Medical officers against which we have several times protested. It further reminds us that the Ministry refused to present to Parliament the reports of the medical officers sent to the Franco-German War, but that a short time afterwards one of our contemporaries professed to have seen these reports in print, and to give some notice of them. Now, it is obvious that the Director-General did not give them to one paper and withhold them from others, after they had been refused to Parliament, and we think he would confer a benefit on the Profession by publishing such parts as would not affect other governments, either in the next Army Report, or as separate pamphlets. The latter would be preferable, and we confidently appeal to Sir G. Logan to consider the matter, and at the same time we hope he will bear in mind that their authors have been shamefully neglected,—so shamefully that the French Government has remarked upon it, and offered them its own Legion of Honour in testimony of their value. This is, of course, useless to them, and only illustrates more fully the injustice of the British Government.

In the name of military surgery we ask for so much of the reports as may be useful. In the name of the surgeons of the Public Services we ask some British recognition of services that have been recognised by Governments and by the scientific world abroad. We have spoken of these points before, and now just as Parliament meets we urge on the Medical Director-General the necessity of some representation on his part on behalf of those of his brethren who naturally look up to him as their head.

A short time since we printed Charles Lever's letter recommending the Peerage for Medical men, and truly there are several who might add wisdom to the Upper House. But look how few and small are the social distinctions which have been given to members of our Profession. Still this flagrant neglect of military men is worse than all, for a trifle has been given to a medical civilian who stayed in Paris during the siege.

A Knighthood has been conferred on Dr. Rose Cormack in recognition of his services to British subjects during that eventful period. We are glad of it, and have previously congratulated Sir Rose Cormack. At the same time we are reminded by this of the shameful manner in which the government has neglected others. The promotion of a physician in civil practice, who stayed in Paris by his own option, while military surgeons, who were there *by order of the British Government* are passed over, evinces a determination to drive all high-minded men from the Public Services. Why the services of Surgeon-Major Wyatt and Dr. Gordon, C.B., the Deputy Inspector-General, sent officially to Paris, were such as to procure for them the special gratitude of the French Government, and yet the authorities at home have not promoted them. Surely it is time for the Director-General to remonstrate against injustice to the best men in his department. Should he fail to obtain a hearing we hope some member of Parliament will exact from the Ministry an explanation of an injustice which cannot but be resented by the 20,000 doctors of the kingdom.

We speak thus for our brethren in the Public Services because they have no other means of making their grievances known, while our contemporaries have indicated the names of a number of civil practitioners who deserve recognition by a baronetcy, a knighthood, or the order of the Bath.

Let us hope that a long list may be gazetted on the day when the Queen goes to St. Paul's to express thanks for the restoration to health of the Heir to the Crown.

◆

THE MEDICAL ASPECT OF THE FRANCO-PRUSSIAN WAR.—No. VI.

The German Administration.—It is probably known to most of our readers that in the Prussian Army the *Etappen* department, in addition to other duties, provides all supplies in the field, and not only so but furnishes the necessary guards for protecting the depots of provisions established at successive points according to the advance of each military force on service, and it is perhaps also known that in raising supplies for individual *corps*, a distinct organisation for the purpose exists in the territorial district to which each belongs.

Some idea of the scale upon which arrangements for feeding the armies in France had to be made if we consider the quantities of various articles required for one corps alone for one day's consumption, namely, 18,000 loaves of bread of 3 lbs. each, 120 cwt. of rice and barley, 70 oxen, or 120 cwt. of bacon, 18 cwt. of salt, 1,000 lbs. of coffee, 3,500 quarts of arrack, 3,500 ounces of essence of bitter orange. Each horse was allowed 12 lbs. of oats, and 24 lbs. of hay and straw, and besides all these, we learn that in one week, there were transmitted along the main line of railway alone for the use of the soldiers 60 cwt. of tobacco, 1,000,000 cigars, 37,400 flannel shirts, 35,000 pairs of stockings, 35,000 flannel belts, and 25,000 blankets. Of the enormous quantities of military stores sent on it is not our province to take count. They have, however, been alluded to by various newspaper correspondents from whose accounts we are enabled to form some idea of the convoys connected with those armies during their advance upon Paris. Thus we read of "innumerable columns of supply, food and provender taking their place with baggage and ammunition," that at one place there were miles of hay-waggons of bacon, and beef waggons, that horned cattle were driven by the score to make beef bye-and-bye, and, indeed, in some instances, the aspect presented by the flood of invasion was likened to what is related in Sacred history of a whole people emigrating and carrying with them their flocks and their herds. As will be observed above, it was not alone in regard to food that the German troops had ample provision made for them; clothes, articles of equipment, blankets, and medicines were all furnished with similar profuseness. But large as were the supplies of the articles in question, they were made use of only as reserves. The Germans seem to have from the first studied how best to make war support itself. As they advanced, *requisitions* were made by them upon towns, villages, and individual houses through or near which they passed, and every private citizen had, as elsewhere mentioned, to supply the number of men who might be billeted upon him with food and drink. It is true that the several armies were each provided with field bakeries and *abattoirs*, these being established at suitable distances along the line of route; yet these were evidently only had full resource to when no *better* arrangement was to be obtained, and here was their ordinary way of proceeding: Before starting on their day's march each man was supplied with a cup of hot coffee; on halting during the march a well-provided *canteen* supplied all their requirements at a moderate expense, and, indeed, so distinct have been the advantages of this canteen service to the comfort and consequent efficiency of the men that special improvements had shortly before the war been introduced into it. When their troops arrived in a village they immediately took possession of the bakeries and butcheries, placed sentries over both, gave the requisite number of trained *artistes* to the original holders of the establishments to carry on the work, *requisitioned* flour and cattle, and then having first supplied their own wants, issued fixed quantities to the inhabitants on presentation of a ticket obtainable at the mairie, and on payment being made for the allowance. The results to the peaceful inhabitants have been described by various writers. "In some instances," says one, "their food resources became so exhausted that even actual starvation overtook them." According to another (*a*), the result was "a pitiful scarcity of food and sudden despair," "not a drop of wine is left, not a crust of bread," and here let the remark be made that these particulars, *sensational* as in their nature they may appear to be, have an important bearing upon our present consideration, which is to indicate some of the more prominent respects in which war inflicts its physical evils upon all who take part in it, whether they belong to a victorious or defeated army, or are merely peaceful inhabitants of the districts which for the time being become the theatre of conflict.

But notwithstanding the wonderful organisation of the Germans and amplitude of supplies with which their armies were provided, there are occasions in which even their means were scarcely equal to the strain put upon them. This took place especially after the battle of Gravelotte (*a*), and the circumstance should have its weight in the minds of those who on occasions are inclined to contrast points of our own smaller organisation with the more gigantic arrangements of continental nations. Indeed, this one instance is alluded to to indicate the impossibility, whatever may be the extent or perfection of a system to invariably meet all requirements in active war, and it is clearly with this knowledge in view that experienced officers insist as they do upon individual soldiers having with them a reserve of food.

In cases where the Germans travelled by rail, arrangements were made at stated places to supply them with refreshments, and the circumstance deserves to be recorded as showing how minute were their arrangements, that in all cases where their supplies were transmitted by means of the railway, each train conveying a sufficient variety of provisions to prevent any inconvenience arising to the troops in the case of an accident occurring to any particular train. Those who marched found accommodation in public and private buildings of towns through which they passed, the inhabitants in not a few instances giving place to them for the time being, and not infrequently having to exist as best they could until the next onward move of the invading forces permitted them to return to their own dwellings. Their billeting system was carried on with the same regularity as other portions of their marvellous organisation. An advance party always preceded the arrival of the bulk of the army at a town selected for their halt or temporary residence. With this party were the several quarter-masters who demanded from the several *maires* a list of all available accommodation for troops and horses. This being obtained the accommodation was portioned off, the numbers of either to be billeted on each establishment written upon the door, so that on the arrival of the main body there is neither delay nor confusion in housing the whole. In some of the towns described the French had shortly before been accommodated when proceeding in an opposite direction, and now the inhabitants themselves made remarks on the different plan adopted by the latter. In their case no such arrangements were made for the accommodation of the men. The officers did indeed attend to their own individual comfort, but the soldiers are left to bivouac in the streets and squares, and only food consisting of bread and such other articles as they could obtain from the people, their clothing insufficient and worn, and their shoes dilapidated. No wonder then that accounts of marauding by them find place in the writings of correspondents and others who have mentioned such matters.

On arriving at the positions to be taken up around Paris, the buildings left vacant in villages and elsewhere are immediately occupied by the Germans, and even in their advanced posts ruined houses and enclosed walls furnished a certain degree of shelter and protection for them. The

(*a*) Forbes. Vol. I. P. 201.

neighbouring fields were cleared of their produce for food, the grain stored for use throughout the expected siege, and *requisitions* for supplies of various kinds levied upon the inhabitants over a zone of fifty to sixty miles in depth (a). Huts and houses of very rude and temporary kind, were, in some instances, run up for the purpose, but for the most part existing buildings or the ruins of those destroyed were amply sufficient for all purposes.

THE SMALL-POX EPIDEMIC IN DUBLIN.

We are favoured by Dr. Kenny, Visiting Physician of the North Union Small-pox Hospital, with the following report of the progress of the epidemic. Dr. Kenny having kindly communicated the facts to us at our request, and without the time necessary to make his statistics quite precise :—

In reply to your inquiries as to the progress of the small-pox epidemic, I beg to inform you that I have received into the sheds since their opening on the 28th October, 1871, to the present date, four hundred and fourteen cases. The greatest number of admissions recorded in one week, occurred in the week ending January 9, 1872, when it reached fifty-two. The following week the number was thirty-nine ; the next week forty-one ; and for week ending at date of last return, Jan. 30th, the number was twenty-seven. I expect about an equal number for current week. The numbers steadily increased up to first named date and have since, as shown, declined. I do not, however, believe that any very definite or reliable conclusions, as to the increase or decrease of the epidemic, can be drawn from the weekly hospital admissions. I have heard from the dispensary medical officers of many cases under their care where the patient objected to go to hospital ; and I have also, on good authority, heard of many cases attended by medical officers of trades' union and other societies, the members of which having their medical attendance and medicine for a small annual subscription, do not care to seek hospital relief, wishing, I suppose to get as much value as possible for their money. I fear it would be hasty to conclude, because the number admitted to the sheds last week, showed a diminution on the week previous, that the epidemic was declining. Where so infectious a disease as small-pox, capable, as is conclusively proved, of attacking those not recently vaccinated, invades a community consisting of so many non-revaccinated individuals, as are to be found in the lower classes of Dublin, where filth is so plentiful and sanitary precaution, even of the feeblest kind, so scarce, I fear it is not likely to depart, without using to a greater extent, than it has hitherto done in the present epidemic, the food provided for it in such abundance. Of the total number admitted into the sheds about three-fourths were primarily vaccinated. The remainder consists of cases which were, without any doubt, never vaccinated, and of cases in which no vaccine mark was discoverable, and in which the patients or those connected with them, could not say if vaccination had ever been performed. As a rule the disease has been of a moderately mild type amongst those who were ever vaccinated, but I have, nevertheless, in this class, met with many cases of the worst form of confluent small-pox, and even in some instances the most fatal form of the disease, viz., purpuric variety. The latter form has, however, been much more frequent amongst the unvaccinated. The death rate has been about 20 per cent. on all cases, but whilst, it is not more than about 10 per cent. of the vaccinated, it is about 50 per cent. of the unvaccinated. I cannot too strongly recommend re-vaccination. I have not had one case of small-pox in a person vaccinated within the last five years, where the operation was performed before the patient had been exposed to infection. I have had six cases where vaccination was done after full exposure to infection, in three of them primarily, and in the other three for the second time. In these cases the vaccinia pursued its ordinary course to about the sixth or seventh day, when it was quietly overhauled by the varioline poison which seemed to have been incubating all the time. The vaccination did not modify the disease apparently, as two of the cases turned out confluent, ending fatally. These cases seem to prove the possibility of the two poisons co-existing, as in all of them the vaccination had taken and followed the usual course up to the period named, when it seemed to recede, and be overpowered by the variola which supersede it and occupy its ground. The chief characteristic of the present epidemic, according to my observation, is the great number of purpuric cases to be met with. In all the cases of it I have seen (about thirty to forty), with the exception of four or five, where the purpuric spots were few in number, and no hæmaturia existed, the result was fatal. I do not think any more terrible form of disease afflicts humanity than purpuric small-pox. Death usually supervenes on what, in ordinary cases, would be the third or fourth day of the eruption, but I have seen it occur on the first day within twelve hours of the patient's admission into the hospital. Properly speaking there is no eruption, or at least, none that closely resembles that of ordinary cases. When any does appear, it consists of minute blister-like elevations of the cuticle, sometimes coalescing all over the face. The appearance of the usual eruption is to be regarded as favourable especially if it reach the pustular stage. The body, especially about the abdomen, flexures of the hip, shoulder and elbow joints is mottled deep purple as though steeped in logwood juice. The conjunctivæ are suffused, expression of the eyes, furtive and anxious, pupils contracted, tongue coated at first with a thin chocolate colour exudation, which gradually thickens into a dark leathery coat, tonsils and uvula enlarged and purple in hue, pulse small and weak, heart irregular in its action, the second sound becoming gradually lost. There is usually, though not always, very severe pain in the loins, and great anxiety expressed in the general demeanour of the patient. There is generally low muttering delirium before death, seldom furious delirium. In some cases hæmatemesis occurs, in very many hæmaturia, and in a few hæmorrhage from the bowels, and in all evidences of intense blood poisoning and prostration. The *post mortem* examinations showed congestion of all the internal organs, the kidneys in many cases being filled with blood of a dark granular character. The most frequent cause of death in all cases not purpuric was, inflammation of the trachea, but in nearly all cases where this was the cause the disease was confluent, and there existed secondary fever quite sufficient to cause death without the tracheal complication at all. Death generally in confluent cases occurs from the eleventh to the fifteenth day from the commencement of primary fever.

Notes on Current Topics.

Chelmsford Dispensary.

This institution, to which we alluded last week, has given rise to further discreditable proceedings. The *Chelmsford Chronicle* of the 2nd inst. contains a number of letters, from which we gather that a Mr. Veley, who appears to be the honorary secretary, has addressed to Dr. Roche one of the most impertinent letters it has been our lot in thirty years of journalism to see addressed by an official to a member of our Profession. We are glad that Dr. Roche has upheld the dignity of his calling by refusing to recognise the right of a secretary to interrogate and threaten any medical man as to whether he addressed a letter to the *Chronicle* or not. We are glad too that our contemporary takes this view of the "very pretty quarrel as it stands." Mr. Veley is we hope only the cat's-paw of the mean committee which as a board has no soul to be saved nor body to be kicked, and which therefore may think it well to beg for advice gratis from all the members of the Profession in the district, and then address to one who refuses, a series of impertinent questions.

(a) Forbes, Vol. II. P. 72.

Why did not Mr. Veley attempt to bully the Editor of the *Chronicle* out of the authorship of the letter that gave offence? Perhaps he knew too well that the honour of the Press was safe in our contemporary's keeping, and that if he went there for wool he would be as well shorn as he has been by Dr. Roche.

The Late Dr. G. E. Day.

We regret to have to announce the decease of this gentleman, who formerly filled the post of Chandos Professor of Medicine at the University of St. Andrew's. Dr. Day was for a long time an invalid, and had resided at Torquay for the benefit of his health. He was a first-class anatomist, and had devoted much attention to the cerebral ganglia, upon which, on one occasion, we well remember he subjected a candidate to examination at St. Andrew's. Shortly after then he had the misfortune to break his arm, through an accident in a mountaineering trip. He suffered for a long time from the non-union of the bone. Dr. Day was only fifty-six years of age. His work on the "Diseases of Advanced Age" has long been the standard one on the subject, and he was also the writer and translator of other scientific books.

Miss Alice Vickery.

We notice that at the Apothecaries' Hall, London, on the occasion of the Examination in Arts, out of 66 candidates 47 passed, and among the successful candidates was a lady named Alice Vickery. This is the fourth lady we understand who has taken advantage of the portal of the Apothecaries to approach the sacred precincts of Medical practice. Mrs. Anderson, Mrs. Thorne, Miss Downing, and Miss Vickery have all graced the Hall by their presence. Probably some of these ladies will take advantage of the Obstetrical Society's Examination.

The Progress of Medical Electricity.

On Saturday evening, Mr. J. L. Pulvermacher, whose name is almost as familiar as a household word in connection with Medico-Galvanic Appliances, gave a Soirée, to which were invited several members of the Profession, and of the Press, who take an interest in the progress of Medical Electricity. There was a goodly number present and the short lecture which was given by Mr. Pulvermacher, who traced the development of the Science of Electricity from its infancy to the present time, was listened to with great interest. This gentleman, although a German by birth, delivered himself in excellent English, and his explanations of the various phenomena produced by this agent, and the illustrations and experiments which were given in a lucid and scientific style, prove him to be a thorough master of his subject. With one thing we were particularly pleased, viz., an utter absence of self. There was scarcely an instrument, either English or foreign, that was not either shown or mentioned, with a proper acknowledgement of the merits of each; in fact his own inventions, which are so well known to the Profession, and deserve to be more extensively used, were touched upon only incidentally, and with modesty. In these days of charlatanism and quackery it is refreshing to observe this feature: an inventor who merges personality in an invention which in the hands of Medical men is capable of so much good, and whose highest aim is to receive a similar acknowledgement at the hands of the Profession of this country to that which has already been accorded to him by the Academy of Sciences and the heads of the Profession in France, deserves the recognition he solicits. Indeed, the Medical literature of France upon the subject seems not to be considered perfect without illustrations and descriptions of his inventions, and we are glad to see also a tendency on the part of writers in this country,—men whose names are a guarantee—such as Drs. Russell Reynolds, Handfield Jones, Powell, &c., to acknowledge the merits of such inventions, and to suggest their more general adoption. From the great success which has attended the treatment of cases which have been brought under our immediate notice, together with the extreme portability and simplicity of the machines, we feel perfectly justified in endorsing the views expressed by these gentlemen, and wish the inventor the success he undoubtedly merits.

Treatment of Small-pox.

In the *Union Med.*, Nov. 1871, we find an account of a paper read by M. Briquet in the Academy of Medicine in October concerning an epidemic of variola which took place in the ambulance of the Rue de Clichy during the siege. This paper aroused an interesting discussion, in which mercurial treatment in variola was shown to be dangerous. Varioloid and cases of discrete variola were left to themselves, and only in cases of confluent small-pox was anything attempted. The topical application of mercurial preparations was made use of in this. The end attempted to be attained was to produce swelling of the face, to prevent the formation of thin layers of pus, which escape through the fissures of the epidermis, occasion much pain, and give the head such a repulsive appearance. Ninety-five small-pox cases with intense eruption were submitted to the application of mercurial topical remedies with the following results:—In discrete variola the inflammation of the pustule either diminished, or was completely prevented; the red areola surrounding the pustule disappeared; the fibro-plastic exudation took place very incompletely. Of 95 patients submitted to this treatment, all of whom were severely attacked, there were 40 cures and 55 deaths. The two inconveniences arising from employing mercurial ointment were salivation and hydrargyrism; the first was pretty frequent, but was not severe; the collyria of Laupauce and gargles made them quickly disappear. Hydrargyrism was very rare. The mortality was zero in varicella, it was 1 in 8 in varioloid, and 2 out of 3 in variola.

Dislocation of the Hip Joint.—Biglow's Method of Reduction

A MUSCULAR man, æt. 31, a surgeon, says the *Lancet*, was brought to the University College Hospital, on account of dislocation of the left femur, caused by his having stepped from a railway-carriage whilst in motion, and falling between the train and the platform as a consequence. Thirteen hours after the accident reduction was effected according to the Biglow method, and in the following manner. The house-surgeon stood on the left side of the patient (the patient lying on his back was placed on a mattress, and the mattress placed on the floor) the limb was first fixed at right angles to the patient's body by the house-surgeon, who then placed his *foot* on the pelvis to steady it, and made a moderately forced traction from the fixed knee. The bone returned to its cavity with a loud snap, the force used was inconsiderable, and the time taken to reduce the dislocation scarcely a minute.

Influence of Movements of the Uterus on the Vomiting of Pregnant Women.

DR. AUBERT (*Lyon Med.*, Oct. 15) says that the pains and accidents attributed to uterine deviations or deformities of the uterus are not due to the sole fact of the deformity or deviation, but are caused by the movements and shocks which the displaced uterus undergoes. In all cases of uterine displacement there are two elements to be taken into account, the anatomical and the locomotor, the first consisting in alteration in position and form, the second in the movements or shocks which the displaced organ undergoes. Both of these appear to be met with in pregnancy. Thus it is found that rest in bed will sometimes cause the vomiting of pregnancy to cease, but not always. Vomiting in pregnancy comes on generally at two periods of the day—firstly, in the morning, when the patient begins first of all to move in the bed, and when she rises. This is the most common time. The early months of pregnancy, too, when the uterus is less intimately connected with the other organs, and thus more mobile, is the epoch of vomiting. The author recommends in some cases the use of pessaries in bad cases of vomiting in pregnancy, in order to keep the uterus motionless.

The Rich Man and Lazarus.

THE last issue of the *Food Journal* affords a study in philanthropy which would be amusing were it not painfully real. We quote *verbatim* from communications which stand side by side.—

"The following is the *carte* of the dinner of a *Journée Russe*, given by a celebrated *gourmet*, at a watering-place in France, before the war:—Potage Palestine à l'Impératrice ; Consommé aux pointes d'asperges ; Petites bouchées Rostégayi ; Saumon du Rhin, sauce Valence ; Langue de veau á la milanaise, &c., &c., &c., with ten wines of the most costly brand.

Nothing could be more *recherché*—one kind of fish, one *pièce de resistance*, and one dish of poultry ; all the rest the very poetry of the *cuisine*—the flowers of the gastronomic garden ; and all sprinkled with the choicest dew that Bacchus sheds over our dusty paths. Twenty-one guests partook of the dainty feast ; and, though half ladies, all were epicures, and did thorough justice to the well-studied *menu* of the great Amphytrion."

"At Netherton, one of the outlying parts of Dudley, are eight cottages. Three of these form one property, which is destitute of any water supply. The people can thus only get water by stealing it at night or by using the contents of a filthy swag, into which the drainage of roads, houses, and stables runs. In the first cottage Dr. Thorne found seven persons, all of whom had had typhus. In the second cottage lived ten persons, members of three different families. Three of these ten were orphans through the death of their parents by typhus. Five of the ten had fever when Dr. Thorne paid his visit, and the other five had recently had it. In one room were two beds. In the first bed was a case of typhus ; yet three other persons, all females, slept in the same bed at night. In the second bed was a child ill with typhus, and three others occupied this bed each night. The second bedroom barely held the bed. In it lay two men terribly ill of fever (supposed to be typhus), and another male slept with them at night. In the third cottage six inmates out of seven had had fever. Truly a nice property this !"

Saccharated Cod-liver Oil.

M. TISSIER, in the November part of the *Journal de Pharmacie et de Chimie*, publishes a method for preparing a granulated saccharate of cod-liver oil, for which he claims several advantages, and which may be flavoured by orange, vanilla, &c. The ingredients are as follows :—

White Gelatine,	4	grams ;
Distilled Water,	25	„
Simple Syrup,	25	„
Finely Powdered Sugar	50	„
Pure Cod-liver Oil	50	„

The gelatine should be cut and placed in a wide-mouthed bottle ; the water and syrup added, and the whole heated in a water-bath until dissolved. The cod-liver oil and the sugar should next be well rubbed up together in a mortar and then the warm solution of gelatine stirred in, the stirring being continued until the mixture is quite cold.

After some time the mass will present the appearance of a dense homogeneous jelly ; it is then necessary to add a sufficient quantity of finely-powdered sugar to form a firm paste, weighing 250 grams. The paste is spread upon a marble slab, divided into small pieces and left for some hours to harden. It is then divided into small pieces the size of a lentil, which, after further drying, become sufficiently firm to allow of granulation in a mortar. The drying of this granulated powder is accomplished on a stove at a temperature of 30° to 35° C. The product will contain one-fifth of its weight of cod-liver oil. It should be kept in well-closed bottles.

The Sad Sequel.

IT is sure to be in the recollection of most of our readers that a short time since a Professional brother, Mr. F. B Eaton, of Nuneaton, was found by the roadside in a dying and unconscious state, having been frozen to death during his return journey from a professional visit. Poor fellow, he has left to mourn his loss and totally unprovided for a wife and three children, the oldest of the children being under three years. Messrs. Nason (Nuneaton) and Wyer (Leamington), will gladly receive subscriptions on behalf of this afflicted family, and we feel confident the Profession at large will warmly and substantially support the object aimed at. Subscriptions handed to us shall be acknowledged and forwarded to the aforesaid treasurers.

Tanacetic Acid as a Substitute for Santonin.

ACCORDING to an article by Fronsina Merletta, in the *Journ. de Ph. et Chim.* cited in the *Pharmaceutical Journal* tanacetic acid is prepared in distilling the heads of the common tansy (*Tanacetum vulgare*); the filtered residue is evaporated to the consistency of honey. Treated with lime and animal charcoal and dried, it is diluted first by water, acidulated with hydrochloric acid and afterwards by acetic acid. The tanacetic acid is deposited in coloured crystals, which are purified by repeated washings in distilled water. It has a sharp, bitter taste. It is insoluble in water, but soluble in alcohol and ether. Nearly all its salts are crystallisable.

The author states that as a vermifuge it operates in the same doses as santonin.

"Woman."

SUCH is the interesting title of a new weekly journal started this week with much vigour, and edited by an able lady Mrs. Amelia Lewis (by birth a German 'we hear). It consists of 24 pages, the size of the *Saturday Review*, and all its articles both leaders and others, have the signatures of the contributors, who are all remunerated. In the Educational Department we notice an article by Dr. C. R. Drysdale on the present means for Medical Education for Women in England and Scotland, and another by Adolph Rolenteau on Medical Education for Women in France. Both contain most interesting facts, and we think that with care *Woman* may live.

The Qualification for Surgeoncy to Irish County Infirmaries.

THE disputed questions in reference to this matter which have been raised in connection with the Kerry Infirmary, came before the Court of Queen's Bench, Dublin, on Friday last, when—

> Mr. W. Hickson moved on behalf of Dr. Lalor for an information, in the nature of a *quo warranto*, against the defendant, with the view of cancelling the defendant's election to the office of surgeon to the County of Kerry Infirmary. It appeared that Dr. Francis Croupe having through ill-health resigned the office in question after holding it for fifty years, notice was given that the Board of Governors, consisting of 17 members, would, on the 28th July, 1871, proceed to elect his successor. On the day mentioned 12 members of the board attended. Three candidates offered for the office. A second polling placed Drs. Alton and Lalor on an equality of votes —6 for each. Dr. Lalor's supporters suggested that the election should be postponed for a larger attendance of the governors, but the chairman, Mr. Sandes, after some hesitation, yielding to the wish of Dr. Alton's friends, gave a casting vote in favour of that gentleman, who, having nominally a majority of one vote over Dr. Lalor, was declared elected.
>
> Dr. Alton was a member of the Royal College of Surgeons, and co-opted by the Royal College of Surgeons in Ireland, in 1844-5; yet not being a L.R.C.S.I., counsel contended that the honorary distinction he obtained did not constitute letters testimonial, and therefore he was disqualified to fill the office of surgeon to an Irish Infirmary. It was also alleged that the giving of the casting vote was illegal. The conditional order granted on both grounds.

As we have already informed our readers the subject of dispute really is as to whether a Fellow of the College of Surgeons, who obtained his Fellowship without examination in the year 1844, possessed the privileges which by the Act of Parliament are conferred on the olders of the "Letters Testimonial" of the College. Dr. Alton contends that by the first clause of the Collegiate Charter, all the rights, "privileges, and immunities" of a member of the Corporation are given to him, and amongst these is the holding of a County Infirmary, while Dr Lalor maintains that as Dr. Alton never possessed the "Letters Testimonial," he is ineligible, and that it never was intended to confer on co-opted Fellows the privileges of Licentiates by examination.

Homœopathic Recantations.

THE conversion of homœopaths to common sense has, as we have more than once pointed out, been recently making rapid progress. Obviously the temper of our day is not with billimeths of vacuity, nor will sick people not spare time for the vagaries of homœopathy when, by the other road, they may help to hasten the unaided efforts of Nature. In the last *Homœopathic Review* Mr. Charles Allen reads the following remarkable recantation:

> "The carefully-recorded results of 860 cases leave no doubt on my mind as to the marked general superiority of the low attenuations of drugs.
>
> "Years ago I used the thirtieths almost exclusively, and I did not find that the most carefully-chosen medicine was by any means to be relied on in cases that required *serious* (*sic*) treatment.
>
> "I tried lower and stronger attenuations with ever-increasing success.
>
> "I now find that, save in rare cases, I can certainly cure my patients with the first centesimal, the first decimal, *or drops of the strong tincture* extended in a proper quantity of water.
>
> "I, for one, would rather follow Hahnemann while in the full vigour of his mid-age maturity, than in the comparatively enfeebled epoch of his increasing senile infirmity.
>
> "I respectfully ask my fellow-practitioners . . . . to remember only that, when Hahnemann was getting very old, he advocated the thirtieth attenuation.
>
> "It can be no indignity to compare one great man to another. Let me, therefore, remind our ultra-Hahnemannic brethren, that even Homer sometimes slept.
>
> "We want, therefore, stern, unflinching truth.
>
> "We may well, then, *after fair trial*, ask ourselves these simple questions :—
>
> "Do Fincke's high potencies cure?
>
> "Does *merc. sol.* 30, cure syphilis?
>
> "Does *sulph.* 30, cure the itch?
>
> "Experience says—No.
>
> "And the utmost that can be urged in favour of high potencies is, that they may cure under certain favourable circumstances of exceptionally exact diagnosis."

We gladly welcome the emergence of any practitioner from the fog of Hahnemannism, but we venture to enquire whether Mr. Allen still continues to call himself a homœopath. It has often been said that homœopathic practice is in many instances a false pretence to satisfy the prejudices of old women who have a taste that way, and who would not willingly submit to medical treatment if they knew it. We hope that such an insinuation is undeserved, and that the whilom disciples of infinitesimalism take care that snuffs of starch and potions of cold water do not get the credit due to medicine scientifically prescribed.

A Specimen of an Irish Pauper.

THE *Nenagh Guardian* publishes a letter addressed by a pauper in the workhouse to the Board of Guardians—a sort of ultimatum statement of the accommodation and privileges which he will accept at their hands in lieu of board and lodging in the union, and in default of which he unequivocally refuses to yield possession. If we may judge of the style of the communication, which is faultless both in orthography and composition, the "man in possession" is a person of education and manners, and apparently well versed both in law and diplomacy. He writes as follows:—

> "GENTLEMEN,—I beg to inform you that it has been intimated to me that my stay in this workhouse is a subject of some concern to the ratepayers of Cullenwane. I therefore think it necessary to also say something on the matter, by the way of reason for my remaining here. It is unnecessary for me to inform the ratepayers above that I have a helpless family—my eldest boy being scarcely strong enough to assist me in daily work. Nevertheless it is only a question of employment with me. On the day I get *permanent* employment I will leave the workhouse. I want such employment to be constant, *otherwise it would not suit me in my present circumstances. Until such as I have now spoken of is procured me, I cannot consent to leave the workhouse, and if they can't get me suitable employment, let them send me to America* (which, perhaps, might be easily done now in connection with free and assisted passages of families, &c.), then I am no longer a tax on their generosities."

It was stated to the guardians that this pauper cost the union £83 a-year. Was there ever a more scandalous misappliance of charity than his maintenance at the public expense?

The Training of Army Midwives.

THE Lieutenant-General commanding at Aldershot having approved of a limited number of the wives of non-commissioned officers and soldiers being trained as midwives at the female hospital, the *United Service Gazette* says that officers commanding regiments in the South Camp and Barracks, likely to be some time at the station, and in which there are at present no qualified midwives, have been requested each to send in the name of a respectable married woman, who has sufficient leisure to afford the necessary time for instruction. The course will occupy about three months. Persons selected must be intelligent, and able to read and write, and must reside in her own quarters. It is proposed to take four into training at one time, and these will be selected from the names sent in. The course of instruction commenced on February 1.

Xylol.

IN Berlin it seems that this hydrocarbon has been used in small-pox with good results.

The *Berlin Klinische Wochenschrift* states that Dr. Zuelzer, of the Charité Hospital, had administered xylol in cases of small-pox, with the most complete success. It is given in doses of from 3 to 5 drops for children, 10 to 15 drops for adults, every hour to every three hours: as much as a teaspoonful at a time has been taken. The most convenient form of taking it is in capsules containing 3, 5, 8, and 12 drops each.

The theory has been broached that xylol is taken up by the blood, and acts as a disinfectant. Absolute purity of the xylol is necessary, as toluol and other analogous compounds do not possess this peculiar action, and it seems there are some practical difficulties in obtaining xylol absolutely pure.

Xylol, or xylene, C_8H_{10}, was first separated from coal naphtha by Dr. Hugo Müller; it is obtained by fractional distillation until a distillate is obtained of about 140° C. boiling-point; this is mixed with sulphuric acid, which dissolves xylol, forming xylol sulphuric acid; this acid is decomposed by dry distillation, and the xylol thus obtained is further purified. Pure xylol is colourless, it has a faint odour, somewhat like benzol, but different, boiling point, 139° C., specific gravity 866.

Iron in Uterine Injections.

IN a discussion on uterine injections, at a late meeting of the New York Obstetrical Society, Dr. Noeggerath believed the subsulphate of iron less dangerous than the sesquichloride, from the use of which he once occasioned a metro-peritonitis.

Progressive Muscular Atrophy.

A CASE of "Progressive Muscular Atrophy, Simulating Glosso-Labio-Laryngeal Paralysis," is related by T. M. Cross, M.D., New York (*Journal Psychological Medicine*), from which the subjoined deductions are drawn:—The motor cells are only partially involved at the origin of the facial nerves. The embarrassment in speech arises from three factors, namely, the weakened tongue, the paresis of the lips, and the paralysis of the soft palate; these, conjointly reacting upon each other, are the cause of all the difficulty in articulation, and are the result of the changes taking place in the nuclei of the hypoglossal and facial nerves. The diminution in the electric contractility of the tongue is directly caused by the loss of its muscular fibre, while the fibrillary contractions which are the precursors of atrophy, together with the loss of power and the lack of dexterity in performing nice manipulations with the left hand, show very plainly that the disease has already the cervical enlargement.

Management of Epilepsy.

DR. BROWN-SEQUARD recommends, in the treatment of epilepsy, the following combination of the bromides of ammonium and potassium:—

℞ Potassii iodidi, ʒj.;
Potass. bicarb., ℈ij.;
Potassii bromidi, ℥j.;
Ammonii bromidi, ʒiiss.;
Inf. columbæ, ℥vj.;

S. A teaspoonful before each of the three meals, and three teaspoonfuls at bedtime, with a little water.

Dr. Robert Bartholow's (*Fisk Fund Prize Essay*) plan of treatment consists in giving a powder, containing two scruples of bromide of potassium dissolved in water, three times a day, and after the cessation of the paroxysms a drachm dose at bedtime only. It is now well known that a patient cannot omit his dose for a single day without danger of having the attacks return, and he cannot be considered exempt until he has passed two years without a convulsive seizure.

To prevent the development of bromism, Dr. Brown-Séquard is in the habit of combining arsenic with the bromide of potassium. Since using this combination, he has not observed so much the debility caused by its prolonged administration. The use of iron, strychnia, the hypophosphates, is also indicated to maintain the health of epileptics during a course of bromide of potassium. The hygienical means consist of abundant food, wine, outdoor employment, and a careful regulation of the moral life.

Extroversion of the Bladder.

Dr. John Ashurst, junior surgeon to the Episcopal Hospital, Philadelphia (*Am. Journ. Med. Sciences*), refers to twenty cases (including his own) in which plastic operations have been resorted to during the last eighteen years, for the relief of extrophy of the bladder. Of these 20 cases, 14 were absolutely successful, 3 were failures (Holmes 2, Wood 1)—the patient's condition being, however, in no degree rendered worse by the operation—while three terminated fatally (Richard, Pancoast, Wood), though in only one (Richard) was death attributable to the interference of the surgeon. Of the 20 patients, 16 were males and 4 females; 13 were under and 5 over twenty years of age, the age of the other two not being mentioned.

Chloral in Asthma.

From the many reports on chloral we select the following from American sources. Dr. W. H. Canaday in the *Ind. Med. Jour.* says :—

"A child, 11 months old, had colitis in the early part of the summer, with frequent relapses since—was enfeebled and emaciated—took measles, attended with an incessant cough, which harassed it day and night, preventing sleep. It took one and a half grains of chloral every two hours, in simple syrup, for a week, which kept the cough quieted. If it were left off for a few hours over the time, the cough would become very harassing, but on giving the chloral again it was soon relieved. After continuing it for a week or more it was afterwards given occasionally, as the cough seemed to require. I have used it in several cases of bronchorrhœa with the effect, apparently, of relieving cough and drying up the secretion; have given it to small children in grain doses frequently repeated, for colic, restlessness, &c., and find it the best soothing syrup that I have ever used."

"A little boy, 3 years old, has asthma, cannot lie down on account of difficulty of breathing; slept none last night, was nursed and carried in his parents' arms all night. Now (ten o'clock, A.M.,) his breathing is very laboured, countenance anxious and dusky, appears to be almost asphyxiated. Gave him fifteen grains of chloral, by estimation, and went across the street to see another patient; returned in an hour, found him asleep and breathing much easier. We left him some powders of pepsin and bismuth on account of indigestion, to be taken every four hours, with from eight to ten grains of chloral half way between, unless he should be hard to awaken, in which case leave it off. Next day he was breathing much better, and was running around in a few days."

"A gentleman, subject to attacks of nephritic colic, which lasts him from a few hours to two days, while suffering from a very severe attack, took forty grains of chloral, and repeated it in two hours, and afterward less frequently, which so far annulled the pain as to rob it of all torture, until the gravel had reached the bladder."

CHLORAL IN PARTURITION, ETC.

Dr. T. Curtis Smith, of Middleport, Ohio (*Med. & Surg. Reporter*), gives the following results of his experience with chloral :—

"In parturition, it is an agent of great value for the relief of pain or to relax a rigid os or perineum. Especially is it useful in those cases where the pain is peculiarly distressing, with but feeble contraction of the uterus and but slight dilatation of the os. During the first and second stages of labour the pain can be greatly diminished or entirely destroyed, without affecting the contractile power of the organ, and labour is often expedited by completing the relaxation necessary. But during the third stage and for a few days after it, I can hardly deem it a proper remedy, for the reason that it allows or causes too great relaxation of the uterus, thus favouring hæmorrhage, which would be difficult to control while the relaxing power of the chloral should last. Now, as the effect of doses given during the second stage must continue into the third, it follows that this relaxation continues, and it becomes the duty of the accoucheur to attend more closely than usual to the contraction of the uterus and the quantity of the discharge that is going on. It has, two or three days after labour, been followed by dangerous hæmorrhage, and must be used under such circumstances with *great care*, if at all. In pertussis and coughs it is a highly beneficial agent, given at bed time, securing the patient good sleep over the night, but during the day, if given in doses large enough to control the cough, its hypnotic power proves objectionable. For pleuritis, pleurodynia, gastralgia, colic, and very painful diseases, I have not found it equal to opium or its alkaloids, but it is very admissible where opium is followed by ill consequences.

"In strangury, intestinal stricture and spasmodic maladies generally, I deem it a highly valuable agent; I cannot, however, speak highly of its value in the convulsions of children, having used it but a few times, and then observing somewhat dangerous symptoms following it."

Aconite.

Dr. S. S. Keene, of Providence, has reported a peculiar case of "Poisoning by external application of tincture of aconite root, through a wound in the index finger of the right hand," describing the effects of the poison, and the remedies effectually applied.

Sir B. C. Brodie will, it is said, resign the Professorship of Chemistry at Oxford. We regret to hear that ill-health is the reason.

Dr. Bradbury, of Downing College, Cambridge, has been appointed Linacre Lecturer in Physic at St. John's College, vice Dr. Paget, recently appointed Regius Professor of Physic.

The will of the Rev. T. Fownes Luttrell, late vicar of Dunster, Somerset, contains the following charitable bequests :—To the Taunton Hospital, £500; Bath General Hospital, £300; Eye Infirmary, Taunton, and the Village Hospital, Dunster, each £200.

Dr. C. T. Gardner, of Providence, reported to a late meeting of the Rhode Island Medical Society a very interesting case of "Hydatid Degeneration of the Kidneys," in a newly-born child, which occurred in his Medical practice, with an exhibition of the diseased kidneys preserved in alcohol. Dr. Gardner gave a full report of the details of the case, which was the third instance in which it had occurred to the same mother, and some discussion followed the reading of the paper.—(*Boston M. and S. J*).

Dr. Thomas C. Lawton has met with a very remarkable case of "Extra Uterine Fœtation." He gave to a society a very interesting account of the case, says the *Boston Medical and Surgical Journal* in which death occurred July 17, 1871, æt. 62 years. A *post-mortem* examination discovered a fœtus at large in the abdomen, which, upon removal, weighed four and a half pounds, and had been considered a movable tumour by nine physicians, which had been borne by the mother for *twenty-nine years*, and always declared by her while living to be a child.

THE United Hospitals' Annual Dinner on Thursday evening last was a great success.

THE Annual Meeting of the Governors of the National Hospital for Consumption, Ventnor, will be held at the London offices this day (Wednesday).

THE communication on "Epiphysary Fracture" in our last, was by Mr. Edward Hamilton, of Dr. Steven's Hospital, Dublin, whose name was by error omitted in its heading.

AT a public meeting held in London last week for the purpose of promoting the Livingstone Search Expedition, the Lord Mayor, Sir H. Rawlinson, Colonel Grant, the African explorer, and Lieut. Llewellyn Dawson, who is to command, were amongst the speakers, and it was announced that the funds amounted to nearly £3,000.

THE illustration which appeared in Mr. Croly's communication on "Bent Knee" last week, was inadvertently inserted there. It had reference to a coming paper by Mr. Corley, on the Bavarian method of treating fractures and will appear with it.

WE are informed that in the course of a few days—probably on Saturday or Monday—their Royal Highnesses the Prince and Princess of Wales will proceed to Osborne for the benefit of the Prince's health. The Royal party will rest at least one night at Windsor on the way down, and will not pass through London at all.

ACCORDING to the quarterly return of the Registrar-General, in the United Kingdom the births of 256,319 children, and the deaths of 175,890 persons of both sexes, were registered in the three months ending on the 31st of December, 1871. The national increase of population was thus 80,429. The deaths were raised to the extent of 7,000 over the average by the severity of the weather; and the mortality was above the average, especially in the towns of the kingdom. Small-pox, owing to the defective administrative arrangements, was, in spite of the Compulsory Vaccination Act, more fatal than any other epidemic; of it more than 6,000 died, chiefly children. Last week in the metropolis 1,602 deaths were registered, being 170 below the average.

THE French Minister for War has, according to *L'Abeille Medicale*, issued instructions that the principal veterinary surgeons of the army shall perform an inspection of the horses belonging to that service both in France and Algeria. In that inspection they will be directed to report upon the actual sanitary condition of the animals, and to assure themselves that all regulations relative to their hygiene are practically carried out. They will further indicate what improvements seem to them to be required in regard to the food of the horses, and take notice in regard to the *personnel* of the veterinary departments. This inspection, which has already begun, is expected to yield useful results to the army and the treasury, as well as to the veterinary body itself.

A NEW ALCOHOLIC DECLARATION.

THE use and abuse of alcohol in medicine has, since the memorable Declaration—which was first published in these columns, and subsequently copied into hundreds of other publications—taken its place amongst the most important medico-physiological questions of the day,—all the more urgent because it is a subject on which the public has formed its own independent ideas, and which the profession cannot therefore debate simply on scientific therapeutic grounds.

The action of a very unscientific *quorum*—an Irish Board of Guardians,—animated by a very unscientific object—that of economising the rates—has put us in possession of a document which, *pro tanto*, is a very significant corollary to the Declaration, and to which we think it right to call attention. The Clerk of the Mountmellick Union submitted to the last meeting of his Board a return, prepared by him at their suggestion with care and accuracy, of the quantity of wine, beer, and spirits consumed in 91 out of the 163 Union Workhouses of Ireland in the last year, and side by side with it a statement of the daily number of persons relieved, the average cost per head for stimulants, the mortality and the percentage of deaths to the number relieved. This return presents the most extraordinary extremes of expenditure. The actual cost of stimulants varied in different Unions from 16s. up to £879 a year, and the cost per head of persons relieved from 0¾d. in Lurgan (where an average of 385 persons consumed only a guinea's worth of stimulants in the year), 1½d. per head in Mullingar, and 2½d. per head in Newtown-limavady, up to £1 5s. 10d. per head in Donaghmore, and 17s. 6d. per head in Urlingford and Rathkeale. In the Unions we have named, and which we take as extremes, the percentage of deaths to average daily number of paupers relieved was—

Lurgan,	35½ per cent. ;
Mullingar,	21 „ „
Newtown-limavady,	20½ „ „
Donaghmore,	18 „ „
Urlingford,	12½ „ „
Rathkeale,	22 „ „

The author of the Report sums up his results in the statement that of 20 unions whose expenditure does not exceed 1s. per head per annum, the mortality is 22¾ per cent.,—in 30 whose expenditure is over 1s. and up to 5s., the mortality is 22¾ per cent., and in 34 whose expenditure is over 5s. the mortality is 25 per cent.

These figures must, of course, be taken *quantum valeant*, and no accurate conclusion can be drawn from them except on a close comparison of the age and health of the paupers in each union, and the proportion of old and sick to able-bodied inmates. So far as it goes, however, Mr. Goodbody's valuable and painstaking report undoubtedly establishes the hypothesis that, as a matter of health and mortality, a large expenditure in stimulants is not justified. There are grounds of humanity on which, perhaps, a moderate ration of stimulants to weak and aged paupers may be defended, but the medical profession is concerned for their health, and a very important and radical issue has been raised, the data for which ought to be official and unchallengeable as to their accuracy, and we, therefore, trust that Mr. Goodbody's return may be the subject of a more comprehensive and conclusive investigation.

SCOTLAND.

EDINBURGH.

On Wednesday evening Dr. Lyon Playfair, M.P., delivered a Lecture before the Philosophical Institution, "On Teaching Universities and Examining boards." The lecturer discussed the views recently announced by Mr. Lowe, at Halifax, and advocated the preservation of the individuality of Universities as teaching institutions, and deprecated the destruction of such individuality through the establishment of Common Examining Boards.

The Infirmary interdict.—Counsel were heard on Wednesday by Lord Mackenzie on the note of suspension and interdict against the March election of Surveyors for the Royal Infirmary. His Lordship has taken the case to *avizandum.*

Dr. Andrew Wood has addressed a letter to the contributors of the Royal Infirmary urging the claims of that institution, and deprecating the idea that the present divisions which have arisen among the contributors upon a certain question will diminish the support already granted to it. Dr. Wood under any contingency is prepared to give a subscription equal to what he originally gave.

Scholarship in Sanskrit.—Dr. John Muir has placed in the hands of the Senatus Academicus of the University of Edinburgh the sum of £100, to be given as a prize to the candidate who shall manifest the highest proficiency in the examinations for the degree of doctor of Science in the departments of Sanskrit and comparative philology at that university. The competition for the prize will be open to graduates in arts by examination (of not more than seven years' standing) of any British or recognised university.

◆

Literature.

LECTURES ON CLINICAL MEDICINE (a).

Valuable as the three preceding volumes of lectures were, we are not sure, but that the present one is superior to the others. It consists of sixteen lectures, chiefly taken up with diseases of the digestive system. Each and all of these are marked by the peculiar features which pervade all the writings of our author. A large and well digested experience; a most extensive knowledge of the labours of others, especially of English writers, including our own Graves, a familiar acquaintance with human physiology; and the whole evidently guided by an intellect of the largest calibre; such appear to us to have been the acquirements possessed by the late A. Trousseau, which naturally placed him at the very head of the French physicians; and which, we believe, he held to the latest moment of his life. It is rarely, indeed, that any one's mind is so gifted, and, when so, turns the gifts to such good account; and we do not know that we could name any other physician who has contributed so many essays of the highest merit: as these must all be allowed to be. No single person could possibly write a complete system of medicine. But our author has gone as far in this direction, or indeed further we may say, than any other physician; and this is no small triumph. To compare him, for instance, with Niemeyer would, it appears to us, be a very great mistake. It is true the latter has written a "Practice of Medicine;" but we doubt much if it will hold its ground; though we are quite aware of its being greatly thought of, and of its author being considered in Germany as the first of physicians. We repeat that we do not look upon the German as at all equal to the French physician. And now, to come to the contents of the volume before us. The first lecture—essay we would call it—is "On Dyspepsia," which the author professes to treat in only an incomplete manner. The reader will arrive at a different conclusion, for the whole lecture is full of remarks of the highest practical value. We observe, too, our author speaks very strongly against those who imagine that they have nothing to do in treating dyspepsia, but to order alkalies if there be over acidity, or *vice versâ.* In other words they look on the living organism as if it were a chemical laboratory, in which their remedies will act similarly. Against this mechanical idea our author protests, and we entirely concur with him; and he not only speaks in this way, but proves by a direct appeal to experience that such notions frequently lead to erroneous practice, and do far more harm than good. But we must refer our readers to the lecture itself about this point. We notice that our author speaks of a remedy, in certain forms of dyspepsia, which has been but very little used in these countries. We allude to the inhalation of oxygen which has been recommended in France, and has succeeded in cases of a very grave character. The author details two such cases where success followed its use, after all other means seemed to have failed. The use of this agent is due to Demarquay, and it is a point of practice not to be forgotten. The second lecture is "On Chronic Gastritis," and it also is excellent in its way. The author enters at some length into the diagnosis between cases of chronic gastritis and cancerous disease of the stomach; a point in practice we need scarcely add, often of the utmost moment to decide. In many cases our author thinks it matter of prudence to suspend our judgment till we have made a fair trial of remedies. No doubt this is a most important rule; for it is certain that cases occur, and, indeed, such are not uncommon in our own experience, where all the symptoms of malignant disease exist, and yet the case is one of chronic gastritis. A very well detailed case of this latter kind is given, where our author thought cancer must have existed, and yet the patient got quite well.

The third lecture is in close connexion with the last being "On Chronic Ulcer of the Stomach," the diagnosis of which is known to be so frequently obscure. The cases detailed, as well as the remarks of our author, are of the highest practical value. We do not observe, however, that he alludes to those cases of the disease where perforation is almost the first symptom which declares itself. We need scarcely add that such cases are always fatal; though one came under our own notice, where, with all the symptoms of perforation existing, and in a profound degree, the patient rallied, and is still alive, after several years. The diagnosis of this case may, of course, have been erroneous. Such cases as these—we mean of perforation—may not be common in France. But they are certainly tolerably frequent in these countries, and occur always, we believe, in young women, and while, to all appearance, in good health. In more than one case we have known the suddenness of the attack, and rapid death, give rise to the suspicion of poison. Our author's remarks apply chiefly to cases where hæmorrhage arose from the ulcer, and this is to be met in both sexes. In this lecture we would specially direct the attention of our readers to the author's remarks on "Melæna."

The two following lectures are occupied with the subject of "diarrhœa" in its several forms. We do not observe any special points to notice; with the exception that our author speaks very highly of the use of raw meat as being of great use in many cases. He uses it in both adults and children, and the fullest account is given of the mode of both preparing and giving it. We notice this plan here, as we believe it is not in as general use as it deserves to be. There is clear evidence of its succeeding after the ordinary treatment had failed, and some cases in illustration will be found detailed. It is worth noting that the use of raw meat has been followed by the appearance of worms, and our author dwells on the fact. The next lectures are on "Lactation," and "Weaning," "Dysentery," "Constipation" and "Fissure of the Anus." Though all good in their way, we do not observe any special points to notice in them. These again are followed by a very valuable essay on "Intestinal Occlusion," in which our author enters very fully into the question of performing gastrotomy; of course, after all ordinary means have failed. This question we consider one of the very highest practical importance, and one which has got little, if indeed, any special attention in these countries. We have both seen and known of cases of intestinal obstruction in which it seemed to us the surgeon would have been fully justified in opening the abdomen. Yet the opposite opinion prevailed, and nothing was done. Our author would not have acted this way, for he advocates the measure strongly. For ourselves the liberties which are, at the present day, taken with the abdominal cavity, and without any bad results, has long since satisfied us of the possibility of success; to say nothing of the frequency with which the abdomen is opened in cases of hernia, and with success. The subject, however, is too extensive to be entered upon here, and we shall only make one remark about it; which is that, in many cases—probably the majority—the strangulation is due to a cause which the very slightest manipulation would remedy; as a slight twist in the bowel, or a knuckle of intestine hanging through an abnormal opening in the mesentery, or a chord of lymph fixed at both ends, and under which a portion of intestine has passed.

(a) "Lectures on Clinical Medicine," delivered at the Hotel Dieu, Paris. By A. Trousseau. Volume Fourth. Translated from the Edition of 1848. By John Rose Cormack, M.D.Edin., M.D.Paris. The *New Sydenham Society, London,* 1871, pp. 470.

With this knowledge in our minds we repeat an operation would be fully justifiable, and the day will, nay must come, when it will be undertaken as a matter of course. No doubt the risk will ever be great; but better to give the chance than let the patient die miserably.

Our space forbids us to do more than name the next few lectures, which are on "Hepatic Colic," "Biliary Calculi," "Hydatic Cysts of the Liver," "Malignant Jaundice," and "Syphilis in Infants." In each and all of these the reader will find many practical observations. The cases given too, and particularly in the first of these, are of special value, and any one who might be at a loss in their diagnosis, will be very likely to get assistance here. Into the intricate subject of syphilis, we do not venture to speak at all.

The concluding lectures of the volume are occupied with gout, and what may be called the allied affections; that is, rheumatism and its varieties. The first of these is of more than ordinary practical value. From the author's great experience and grasp of mind, we do not know there is any lecture in this volume of more importance than the one which treats of gout, both in its regular and anomalous forms. We observe the author is entirely opposed to any treatment which can interfere with the regular attack of the disease, and on this point of view he has many to support him. For ourselves we believe gout is to be treated as well as other diseases. But we do not mean by this that any vigorous measures are to be adopted, such as what are understood as the antiphlogistic treatment. We have known patients try and bear an attack of gout, to let it burn itself out as the expression is. But very few are able to endure to the end, and we repeat that gout, like other affections, may and ought to be treated, and with ordinary discretion can be brought to a termination much sooner than if left to itself. When, however, gout becomes chronic, our author does not hesitate to treat it, and all he says is excellent and to the point. In the use of alkalies and alkaline waters, he considers that great caution ought to be used, else that mischief will surely accrue. Indeed, we have ourselves known patients return from the alkaline Spas not bettered in any respect. The fact is, they do not suit all constitutions, and in some they certainly disagree. Yet the feeling is, that a gouty patient has nothing to do but visit one of these places, and get well at once. Our author, we should add, approves, in chronic gout, of the limited use of colchicum, by which he means its being prescribed for three or five days at one time. He also combines with it both quinine and digitalis. The next lecture is on "Nodulear Rheumatism," which our author considers to belong to neither gout nor rheumatism; but to be a disease *sui generis*. Like all the preceding lectures, this one is almost exhaustive, and will well repay perusals; as will also the last one in the volume on "Acute Articular Rheumatism, and ulcerating Endo-Carditis." This lecture is not so much occupied with the subject of acute rheumatism, as with the varieties the disease exhibits, and the more unusual complications met with. Besides those of the heart and chorea, we have affections of the brain, described with embolism, phlebitis.

Our author does not seem to have a preference for any special plan of treatment. Speaking of the alkaline, he hopes it may prove as successful as it has been stated to be; and to the opiate plan of treatment no allusion whatever is made. Still, if the heart get affected, he advises both local bleeding and blistering to be at once used.

We have thus given the very briefest sketch of the chief contents of this volume. Possibly, what has been said may have been enough to induce our readers to peruse it for themselves; and we venture to say their time will not have been thrown away, and they will arise from its perusal with the conviction that they have been in company with one of the master minds of our Profession.

GUIDE TO THE STUDY OF THE MATERIA MEDICA.

Dr. Alexander Harvey and Dr. A. Dyce Davidson, joint professors of materia medica in the University of Aberdeen, being impressed with the exceeding great number of articles and preparations that have a place in the Pharmacopœia have arranged for the guidance of students a very useful little pamphlet wherein the articles and preparations of the Pharmacopœia are printed according to their relative value.

The pamphlet is in fact, as its authors state, a *catalogue raisonné*. Of the primary articles of the materia medica four degrees of value have been assumed, and these are indicated by four different forms of type. In the same way the Galenical preparations have assigned to them a higher and lower degree of value, and any member of the higher or lower division to which it is desired to draw special attention is indicated by an asterisk (*).

Opinions will, of course, differ as to the values assigned to articles and preparations, this is unavoidable, but of the great use of this little book to students there can be no question; a single glance down one of the pages shows at once all the most important names by the character of the type, while the remaining less important members on the list are enumerated in type of less conspicuous form.

The book is dedicated to Dr. Parkes, of Netley Hospital, and in the short introduction will be found some good hints for teachers of materia medica.

A MEDICO-LEGAL CURIOSITY

COURT OF QUEEN'S BENCH.

February 2nd and 3rd.

WILLIAMS V. THE CAMBRIAN RAILWAY COMPANY.

This was an action to recover £174 5s. 3d. for medical advice, &c. The defendants had paid £90 into court, but disputed their liability as to the remainder.

Mr. Lopes, Q.C., and Mr. Charles were counsel for the plaintiff; Mr. H. James, Q.C., and Mr. Turner were for the defendants.

The plaintiff was a medical man residing at Aberystwith, and on the 2nd November, 1869, he was called upon to attend professionally a gentleman named Dashwood, who had received serious injuries in a collision on the defendants' line at a place called Carno. The plaintiff's case was that his charge was at the agreed sum of ten guineas per week, Mr. Dashwood having been removed to Llanysillea, with Miss Dashwood, who was slightly injured in the same accident, about four and half miles from Aberystwith. Mr. Dashwood's injuries were such as to require almost daily attention for seventeen weeks, nine weeks of which time he was confined to his bed. The charge included attendance on Miss Dashwood and another passenger, who was also injured.

In cross-examination by Mr. H. James, Plaintiff stated that at the request of the company he sent in a bill of particulars. In it he had charged at the rate of 755 doses of medicine, 73 lotions and outward applications, and 100 pills and powders, supplied to Mr. Dashwood; and at the rate of 222 doses, 9 powders, and 44 lotions for Miss Dashwood, in seven weeks. There was also an item in the bill for correspondence with Mr. Elwes, the traffic manager, in 25 letters both ways, each at the rate of 10s. 6d. per letter.

He had made the charge of 25*l.* to the station-master at the Bow-street Railway Station, for attendance, &c., but never expected to receive anything; the man offered to pay him in cauliflowers (laughter). He planted him a quantity, and they had all rotted (laughter). The man also paid his tailor's bill with cauliflowers (renewed laughter). This was the first time he had attended a patient under contract. His charge for visits and medicines varied from 5s. to 7s. 6d. per visit in Aberystwith. He sent in the bill to show what really had been done and not for the purpose of charging. He knew he gave all the medicine (laughter), and the charges were fair and reasonable.

Mr. Payton Dashwood said he negociated the settlement of the compensation for his brother, Mr. Arthur Dashwood, who was the person injured. The amount of compensation received from the Company was £375. Mr. Elwes then told him the medical attendances came to £120 or £130, which he urged was a reason why the Company should pay less compensation, but he (witness) said he considered it as a reason why the compensation should be greater, as showing the serious character of the injury. Mr. Elwes said he should have to get plaintiff to take less than ten guineas per week. The injury turned out more serious than was expected. The family were highly satisfied with what the plaintiff had done for his brother. By arrangement with Mr. Elwes, plaintiff was to attend his brother until he was able to travel to London.

After two or three medical men in the neighbourhood had given evidence for the defence, alleging excessive charges by Dr. Williams, the jury ultimately returned a verdict for the plaintiff for £10 in excess of the amount paid into court.

The case certainly presents a ludicrous, and perhaps not very creditable aspect in regard to the enormous quantity of drugs which the unhappy patients are alleged to haveneigest

A dose of physic and a rubbing of liniment every hour and half for a hundred and twenty working days, must inspire at least amazement, and admiration for the iron vigour of the patient's constitution, if it does not say much for the purity of the doctor's surgery. But we don't see that his claim can be disputed on that ground. Dr. Williams was admittedly retained by the Company to attend the patient until his return to London, and he did so to the avowed satisfaction of the patient, though, perhaps, with over-much assiduity to please the Company. It does not seem to be denied that the thousand and eighty-six doses of physic, and the hundred and seventeen lotions were supplied; whether they were necessary no one but the doctor can be the judge, and whether they were taken none but Heaven and the patient's stomach can tell, and we don't at all see how the Company could expect to be allowed to repudiate their ten-guinea contract, or to assess the quantity of medicine which a man may take and live.

THE VITAL STATISTICS OF IRELAND.

Births.—The births registered during the quarter afford an annual ratio of 1 in every 39·5, or 2·53 per cent. of the population.

Deaths.—There were 17,585 deaths registered during the quarter, an annual ratio of 1 in 76·6, or 1·30 per cent. of the population. The average number registered during the corresponding quarter of the previous five years was 18,575.

It is but too apparent from the foregoing figures that the registration of births and deaths is still very imperfect, the annual ratio of births to the estimated population in England being about 1 in 29 or 30, and of deaths, 1 in 44 or 45; whilst in Ireland, according to the present return, the ratios are—for births, 1 in 39·5; and for deaths, 1 in 76·8. The registration of marriages under the provisions of the 26 and 27 Vic. cap. 90, it is greatly to be regretted, is still more unsatisfactory.

The average number of persons in Ireland receiving indoor relief on Saturdays during the third quarter of the present year was 41,332, against 43,751 for the corresponding period of 1870.

The average weekly number of persons receiving outdoor relief during the quarter was 23,744 against 20,292 for the third quarter of 1870.

Health of the People.—According to the number of deaths registered during the quarter, the public health was in a satisfactory state. The registered deaths show a decrease of 990 as compared with the average number in the corresponding quarter of the previous five years, and are 704 less than in the third quarter of the year 1870.

Scarlet fever and small-pox were very prevalent during the quarter. Scarlet fever was generally epidemic; 75 registrars noted the presence of this pestilence in their several districts.

Small-pox has been steadily spreading in various parts of the country. Twenty-three of the registrars report upon the appearance of the disease in their several districts. Two cases of confluent small-pox were imported into the Forkill district, Newry Union, from Middlesboro'; they both, however, recovered.

Fever, especially typhoid, prevailed in some districts. In Tullow district, Carlow Union, "several cases of relapsing fever occurred; 1 only fatal in an aged and broken-down subject." A death from relapsing fever occurred in the Castleblayney district.

Improvements in the sanitary condition of certain localities have been reported, while some districts appear to be in a sadly neglected condition. The Registrar of Castlegregory, Dingle Union, states "that scarlatina prevailed at Magharees and in no other part of the district. Some children died from it. The severity which characterised it there may probably be ascribed to the excessive filth of the villages, and to the almost total want of good water in every part of that sandy peninsula." Seven other Registrars have made reports equally unfavourable as to the sanitary condition of their districts.

NUMBER OF BIRTHS AND DEATHS IN EACH OF THE FOUR PROVINCES.

Births.—There were registered in Leinster during the quarter, 7,845 births, or 1 in every 42 of the estimated population; in Munster 1 in every 40 of the estimated population of the province; in Ulster, 11,921, or 1 in 39; and in Connaught, 5,597, or 1 in 38.

Deaths.—The deaths registered in Leinster during last quarter amount to 5,026, 1 in every 65 of the population; in Munster, 4,512, or 1 in 78 of the population; in Ulster, 5,906, or 1 in 78; and in Connaught, 2,141, or 1 in 98. The average ratios for the third quarter of the years 1866-70 were—Leinster, 1 in 61; Munster, 1 in 75; Ulster, 1 in 75; and Connaught, 1 in 96.

Foreign Medical Literature.

BOUCHARDAT ON THE EVIL RESULTS OF EXCESS OF MENTAL LABOUR AND THE MEANS OF REMEDYING IT.

(Translated for the MEDICAL PRESS AND CIRCULAR by B. BERTRAND, *Professeur de S. A. Mgr. le Prince Impérial.*)

THE principal evil result of excess of intellectual work is that it induces a neglect of bodily exercise. Men absorbed by the workings of their mind forget their body; they forget those opposite cares required by human duality. The principles so admirably laid down by Plato are transgressed every day.

This neglect of the body among brain workers is especially common in France; it is far less so in England. In this latter country the aristocracy has maintained itself, because several old families have retained their vigour in consequence of the equal care they have bestowed on their mental and physical development. The English gentleman fortifies his mind by study, and his body by daily exercise. I will sketch slightly the principal dangers incurred by neglect of bodily exercise by those persons whose lives are spent in intellectual labour, or in any sedentary occupation.

The class of society in which intelligence is developed by exclusive intellectual exercise, is generally one which enjoys that modest competence so favourable to health, and which understands best how to shelter itself from such dangerous excess.

In spite of these favourable conditions, old age is too frequently premature, and death comparatively early in this privileged class. Cancer of the stomach occurs more often in this than in any other class.

Over excitement of the nervous system is one of the causes of the frequency of certain forms of insanity. There is also another which I ought to mention, although it is little noticed, I mean, inordinate pride.

The exclusive care bestowed on the mind, and the neglect of due exercise of the body, leads inevitably to loss of strength. Then in consequence of marriages between individuals infected with hereditary disease, one observes the lowering of the physical level of races, which at last become extinct after a very limited number of generations.

I cannot repeat too often that perfection is only to be attained by a due division of time, in order to reach by physical and mental exercise that harmonious development of all our faculties, and of all our organs. Nothing is easier; in order to succeed we have only to resolve not to squander our time. Let us never forget time wasted is life wasted.

Correspondence.

THE INFLUENCE OF MARRIAGE UPON HEALTH.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—As you have mentioned, M. Bertillon has lately given to the Academy of Medicine of Paris, a statistical confirmation of what had *à priori* been clear enough to all thinkers of note, that the unnatural life of abstinence from marriage is very fatal to the celibate population. M. Bertillon having had to draw up a paper on the influence of marriage on mortality, consulted the registers of the only three countries in Europe which were carefully enough kept to give him a reply to his question, those of France, Belgium, and Holland, and shows that if the male sex be first considered, we find that from 25 to 30, of 1,000 married men furnish 6 deaths; 1,000 unmarried, 10 deaths; and 1,000 widowers, 22 deaths. From 30 to 35, of 1,000 married men, 7 die; of 1,000 unmarried men, 11½ die; and of 1,000 widowers, 19 die. From 35 to 40 of 1,000 married men, 7½ die; of 1,000 bachelors, 13 die; and of 1,000 widowers, 47½ die; and so on at all the following ages, the married man continues to live with greater facility than the bachelor. It has been said that since the most fortunate men can afford to marry, it is not astonishing that these persons should live longer. But this will not, of course, account for the very great mortality of widowers at all ages, which, indeed, surpasses that even of bachelors. Insufficient exercise of a vital function, doubtless, is *the* cause.

However, it must be noticed that 8,000 young men marry in France yearly, under the age of 20. This is very fatal to such young men, for M. Bertillon finds that, whilst 1,000 young men from 15 to 20 furnish 7 deaths, when unmarried, no less than 50 deaths occur among 1,000 young married men under 20. Hence he says with Hufeland, that "the *premature* exercise of the generative organs is the surest way to innoculate old age," a sentiment which all will endorse.

Women seem to reap less advantage from marriage than men, and there is but little difference in the mortality of unmarried and married women before the age of 25. It is but little marked even between 25 and 30. From 30 to 35, out of 1,000 spinsters, 11 die; and of 1,000 wives, 9 die. This difference augments up till 55 years of age. Thus, from 50 to 55 years of age, 1,000 wives have 15 to 16 deaths a-year, whilst 1,000 spinsters or widows, have 26 to 27 deaths. This advantage rests very marked beyond this age, although it diminishes a little; but before 25 years of age in France, and before 20 in Paris, marriage, far from being favourable to the life of women is injurious to it. The mortality of maidens from 15 to 20 is 7·53 per 1,000; of wives of the same age, is 11·86 per 1,000; and the mortality of married women from 20 to 25 being 9·92 per 1,000, the mortality of maids of the same age is 8·32.

Thus, gestation causes some dangers to women, more in Holland than in France. In Holland, 1,000 married women produce 330 children yearly; in France, 1,000 women produce 210 children yearly.

With respect to widowhood, from 25 to 30; widowhood is injurious to health; and whilst 1,000 wives and maids of this age furnish 9 deaths a-year, 1,000 widows have 17 deaths.

But in France, and especially at Paris, this mortality quickly diminishes, and at 45, the death-rate of widows is lower than that of spinsters at the same age. And at this age women who have had children are least attacked by death. "Thus marriage in women retards old age, and soothes its sufferings."

The conclusion of these statistics is that marriage is an element of health much more powerful than has been supposed, that it exercises its salutary influences especially on the male in the age of vigour, and on the female in her declining years. A calculus of probabilities shows that the man who marries between 20 and 25 has 40 years to live in place of 35, and that the young woman who marries between 20 and 25, has 40 in place of 36. Criminality and suicide are far less common among the married than the single, and insanity is less common.

What, then, must we say of all this evidence? Does it not inevitably lead us to condemn the common custom of late marriages, which is so well-marked a feature in this country? Certainly, in all respects but one, early marriages *are* beneficial to life and happiness. That one exception is the danger of bringing into existence numbers of children in excess of the capabilities already accumulated to feed and employ them. It is seen, too, from M. Bertillon's statistics, that marriage is dangerous to young men under 20. The result of these facts would seem to make any person who cares for scientific reasoning arrive at the conclusion that, after 20, marriage should be almost universal, in order to secure the "greatest health and happiness," whilst families should be as small as is compatible with the keeping up of that population which is required for the division of labour of modern times. Those who have had to think often on this question, will feel gratified to M. Bertillon for giving some precision to their language on this very interesting point of human life.

Those of the Medical profession who have occupied themselves with questions of public and private hygiene, must have long been aware that a certain amount of obscurity has existed in that part of the science which relates to the functions of generation, and that a good deal of contradictory evidence has been put forward by men of note to justify the rules they have laid down for the conduct of individuals with regard to marriage or celibacy. It has of course been long known to most men of science that whatever leads to over-rapid multiplication of the race in already peopled countries, tends to produce early death, especially in the form of increased mortality among children, and epidemics of fever and disease produced by under-feeding. Mr. Alexander Bain truly says, in an essay on "Happiness," "the public registers have demonstrated that mortality and disease diminish at every rise in the scale of wealth." M. Levy, in his treatise "On Hygiene," too, says, "It is too true that the duration of life is by no means equal in the different classes of society. Some attain on an average seventy years of age, others do not go beyond forty-five." Consumption, according to D'Espine, occasions 68 deaths per 1,000 among the rich, and more than 230 per 1,000 among the poor. All this mass of evidence has justified the expression of Mr. J. S. Mill, "that, little advance can be expected in *morality* (*i.e.* public happiness) until the production of a large family is looked upon in the same light as drunkenness." ("Princ. of Pol. Econ.," vol. i.)

The writer quite accepts this rule of conduct as laid down by Mr. Mill, as a deduction from the facts adduced by Malthus, Villermé, and the whole body of scientific economists of the 19th century, but it would appear that Medical men have something more to say on this subject in order to complete the theory of Malthus, Mill, and their school. Thus, it has been known for many years from the writings of Levy, in France, and Dr. Farr, in this country, that the mortality of married persons was less than that of celibates, and this has been accounted for by some physiologists by supposing that the non-exercise of the reproductive functions was apt to lead to derangement of the whole economy, with earlier decay and death, a view quite in accordance with the writer's belief. But many able men have dissented from this deduction from the ordinary principles of physiology, among whom may be mentioned Dr. Carpenter, Mr. Wm. Acton, and, among literary men, Mr. F. W. Newman. Dr. Carpenter, in his advocacy of prolonged celibacy as innocuous, seems to consider that the "development of the individual is opposed to the reproduction of the species," and *vice versâ*. Dr. Chapman and Mr. Herbert Spencer may be cited as holding somewhat similar tenets. Mr. W. Acton, a gentleman who has done so much good service in all questions relating to the difficult questions of sexual disorders, says in his most interesting work ("On the Functions and Disorders of the Reproductive Organs"), "under the age of twenty-five I have no scruple in enjoining perfect continence." Mr. F. W. Newman, whose opinions this writer should not think it worth while to advert to in a grave medical journal, were it not that he has seemed to influence one who has done so much as Mr. Acton, has written a pamphlet on the "Relation of Physiology to Sexual Morals," in which, after denying the induction called the *Law of Population*, he rushes into all sorts of crude speculations as to the superior splendour of chastity. Mr. Newman has, however, lived too late, and the ascetic days of monasteries alone were suited to enjoy his dogmas upon subjects he is by education utterly unfitted to propound. All physicians and surgeons of large experience who have kept their eyes open, know well the manifold evils which result from prolonged celibacy in both sexes. Males, they know, have recourse to prostitution, and contract syphilis in immense numbers; females, especially of the upper classes, too, are much addicted to masturbation, when unmarried, to the great detriment of their health of mind and body. Nor has anyone ever doubted the enormous evils caused by masturbation in the male sex since the writings of Tissot and others have pointed them out.

I am, Sir, yours, &c.,
Charles R. Drysdale, D.M.,
M.R.C.P.L., F.R.C.S.E.

ON THE INFLUENCE OF ERGOT IN MIDWIFERY PRACTICE.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—In the last issue of your valuable journal there appears a communication from the pen of Dr. M'Keogh, of Thurles, on the above subject, in which he compares the result of a case as met with in his own practice, where he administered the ergot with one as related by Dr. Sheil, of Killyleagh, in a letter which appeared in your paper, of 15th November.

Now, Dr. Sheil in his report of the case, states, "there was not the slightest return of pains, notwithstanding repeated doses of ergot," whereas Dr. M'Keogh in his letter, says, "I gave her *forty drops* ethereal tincture of ergot; pains soon returned, and with very much force, and in precisely *one hour and a half* afterwards she was delivered safely of a large, well-developed, male child, which was in a semi-asphyxiated state, &c." Further on in his letter he says, "When only a single and so small a dose of ergot, and in so short a time, produced such effects as in this case, I am grieved to think what it might not, or rather ought not, have produced in a case where *several doses* of it were administered, and so left for a space of *three* days! Perhaps it is all owing to indiosyncracy."

Now, Sir, would not the difference in the result of these two cases (as far as the administration of the ergot is concerned) seem to prove the opinion of those authors who advocate the theory, that the injurious influence of ergot on the fœtus is due to its causing very powerful or incessant interim contractions, and thereby interfering with the circulation through the umbilical cord, rather than to any idiosyncracy of the patient or other tonic effects.

I am, Sir, yours truly,
Thos. Fearon.

Warrenpoint, 27th Jan., 1372.

FLANNEL IN OBSTETRIC CASES.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—In order to avoid chills, catarrh, rheumatism, &c., woollen materials are worn in contact with the skin. Chamois leather strikes coldly when damp. Systematic wet-packing cannot be efficiently practised in midwifery cases, although it is true that blankets duly applied palliate the ill-effects of exposure to cold wet. Yet strange to say in the lying-in room the parturient female is permitted to remain hours together with drenched linen or cotton underclothing. The obstetrician in the course of his duties finds the under garments remarkably cold and uncomfortable, and orders extra covering. It would be well to institute a radical change, and insist upon the uniform use of flannel, merino, or other woollen fabric in napkins and dressing-gowns. These remarks apply also more or less to patients suffering from incontinence of urine, and to surgical cases in which wet-packing is inapplicable. Colds, fevers, mammary abscesses,—the latter perhaps rarely—may be occasionally attributed to no other cause than this wearing during long hours clothes or linen saturated with the liquor amnii, or the lochiæ.

I am, &c.,
Hanslip Sers, M.R.C.S.

SCROTAL HERNIA WITH COMPLICATIONS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—The *post-mortem* appearances in the following case may interest some of your readers:—A gardener had a long-standing scrotal hernia, for which of late he had been wearing an inefficient truss. On the Friday, when lifting a heavy frame, he felt a strange sensation at the seat of the rupture in the left side, and from that time the rupture never came down. He continued well, the bowels being relieved, till the following Monday, when he sent for us. He was then suffering with sickness, pain, and constipation; there was a decided fulness and some induration in the left iliac fossa, but the finger could be readily passed along the inguinal canal, and the internal ring plainly felt. An exploring operation was thought not desirable and was objected to by the patient. He lived about ten days. At the *post-mortem* examination the hernial sac with its contents was found lying within the abdominal wall in the iliac fossa. The neck of the sac was *puckered and unyielding*, and about the size of a shilling. The sac was about as large as a fist, and contained a dark fluid, several inches of intestine, which was very dark but smooth and glistening, and a portion of omentum. The omentum was firmly attached by old adhesions to the lower portion of the sack. These attachments may account for the passing up of the hernial sack itself along with the contents into the abdomen. It may be remarked that pressure and manipulation in the locality of the hernial sac gave very little pain. To those of your readers who may remember the case narrated by us, in which a large number of hydatids were removed through a trochar passed into the abdomen, it may be interesting to know the case terminated in complete recovery. We are, yours obediently,

McNab and Fowler.

Epping, Feb. 1st, 1872.

P.S.—Can any of your correspondents disprove the statements of an old writer, that the expansion and contraction of the brain is a primary motion, and that respiration is not the cause but rather a consequence of this motion of cerebral substance? D. R. McNab.

VISCERAL SYPHILIS AND ITS TREATMENT.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—This interesting monograph on "Visceral Syphilis," by Dr. Prompt, has been translated from the *France Medicale*, by a student of the Apothecaries' Hall, A. Vickery, and is so interesting that I send you it for insertion, if you think it will suit your columns.

C. R. Drysdale, M.D.

January 31st, 1872.

Few questions have given place to so many researches and difficulties as that of visceral syphilis. The diagnosis is sometimes extremely difficult; the cause is obscure, the nature doubtful, and the treatment uncertain. It is for this reason that, in the cases where we meet with internal lesions of a suspicious nature, coinciding with well-marked specific antecedents, it is necessary often to be on guard against the *axiom post hoc, ergo propter hoc*, which reserves to observers the most grievous mistakes regarding visceral syphilis; it may be said that the *post-mortem* examination alone permits an absolutely rigorous diagnosis. As to the first origin of these accidents, there is at the present day, a general tendency to attribute them to syphilis itself; however, one is obliged to make some reserves on this subject, when one finds a clinical writer as eminent as Dr. Graves, consider the anatomical alterations which are observed at the *post-mortem* in inveterate syphilitic cases, not as the result of the venereal malady itself, but as the effect of the mercurial treatment, of which the subjects of this kind of disease have always made a veritable abuse. And, admitting that it may not be thus, and reserving to the constitutional lesion the etiological rank which, without doubt, belongs to it in effect, there remains still among the majority of patients a considerable incertitude on the true nature of the morbid phenomena. When the phenomena are reduced to the formation of visceral gummata, that is to say to accidents which their anatomic form invests with a special character, we are then forced to give them a place in the picture of tertiary syphilis. But what shall we say of amyloid degenerations? Is it necessary to attribute them to syphilis itself, or to the cachectic stage occasioned by syphilis? If we reflect that they are encountered equally in marsh fevers, scrofula, and cancer, we have a natural tendency to suppose that they are a result common to a crowd of maladies entirely different in their nature, and that it is not permitted to see in each case a specific effect. On the other side, the actual imperfection of pathological anatomy ranges in identical groups, formations very diverse from a physiological point of view; syphilis itself furnishes us a striking example of this insufficiency of our means of observation; thus, between a cutaneous tubercle of syphilis and a cutaneous tubercle of leprous elephantiasis, magnifying glasses show no essential difference. Certainly a day will come when fine anatomy will emerge from this state of barbarism and inferiority; but, awaiting this epoch, we are obliged to be on our guard against the identities which the microscope seems to establish between facts; and it is wise to repulse until a new order of things, all the practical consequences which might be deduced from the use of this instrument. Notwithstanding this, the treatment of visceral syphilis is and will be still for some time uncertain; the anatomic data is a starting-point too seductive for the mind not to seek to attach itself to it, even in cases where it is not laid down with precision; as long as there can be any doubt if visceral syphilis is really syphilis, as long as there exists an apt anatomical doctrine to favour therapeutic hesitation, they will willingly refuse to anti-venereal agents the confidence which they would accord to them if their ideas were better fixed on the real nature of the malady.

M. Hardy has in his service at the Hospital of Saint Louis, an interesting patient, on whose account he has been called practically to resolve this grave question of treatment of visceral syphilis. The patient is in bed No. 31 of the ward Saint Jean. On examination, one is first struck by the livid taint which is spread over the features. This lividity contrasts with the normal colour of the rest of the body; it is a greyish yellow, and gives to the physiognomy a miserable aspect, an expression of suffering, and exhaustion. The cheeks are thin, and the eyes sunk in their orbits. The expression is vague and wearied; the lips are very pale, the conjunctiva is bloodless.

The abdomen presents a uniform tumefaction, not very considerable, in which one recognises without trouble the habitual signs of ascitic effusion. The inferior members are œdematous, but not very much so. Otherwise the anasarca and ascites are to-day in process of diminution.

M. Hardy has observed both in the patient in a much greater degree of intensity, and has seen them diminish little by little, thus we will say to the present time, in proportion as a gradual amelioration is produced in the whole of the symptoms by the effect of the treatment which he has instituted.

In examining the urine, M. Hardy has recognised that it was albuminous. Lastly, the volume of the liver is not normal, which gives rise to a suspicion of cirrhosis, or some analogous lesion of this organ.

The patient does not conceal his syphilitic antecedents; he carries irrefragable marks of it, which, did he desire it, would renders his confessions useless. These are very extensive, white, slightly depressed cicatrices occupying especially the external face and anterior part of the arms, which, for an exercised eye, leave no doubt about the previous existence of cutaneous alterations of a specific nature.

M. Hardy is of opinion that this is a case of visceral syphilis, and that there is in the viscera, and especially in the kidneys, amyloid degenerations more or less considerable; this would be, therefore, a grave and inveterate case, belonging to the class which Virchow professes to designate under the special name of quarternary syphilis, because there is an intoxication more generalised and more perfect than in cases where the disease, after having exercised its ravages on the skin and mucous membranes, and on their neighbouring lymphatics, is carried to the muscles and skeleton, and limits there its action in a definite manner.

Regarding treatment, M. Hardy has rejected the use of specifics; he has limited himself to the administration of tonic medicines, combined with repose, and a nourishment as abundant as the parsimonious traditions of the administration of the *Assistance Publique* will permit. Under the influence of these means, the patient has regained some strength; he has seen the serous effusions which were produced in the peritoneal cavity, and in the cellular tissue of the inferior members. M. Hardy considers this success as an additional proof of the exactness of his diagnosis. He admits that visceral syphilis is a relatively mild affection, which tends of itself towards cure, when it is submitted to proper treatment; that is to say, when therapeutics, properly so-called, are suppressed, to limit the treatment to indicating to the patient an appropriate hygiene. This is no because M. Hardy agrees with the adversaries of mercury. He follows the errors of the ancients, and administers mercury and iodide of potassium in the immense majority of cases where he has to deal with venereal affections. But he judges it more advantageous to abstain when the evil presents a generalisation and exceptional gravity.

This practice is followed, in our days, by many syphilographers whose ability cannot be doubted. Thus we have seen M. Bazin institute with success tonic treatment in grave syphilitic rupia; and it is remarkable that the indications for mercury are restricted more and more, in proportion as a more exact recognition of venereal maladies has been acquired. In the time of Hunter, the least gonorrhœa was, for the majority of practitioners, a sufficient motive for having recourse to mercury and its compounds. Little by little, we have cut off gonorrhœa, the soft chancre, and the primary accidents of syphilis from the domain of this heroic medicament. The grave tertiary accidents, the quarternary accidents, have been detached in their turn;

lastly, we have been present recently at the debates provoked by M. Armand Desprès, which tend to nothing less than the refusal to mercury of all useful action on venereal diseases, under whatever form, and at whatever period they present themselves. This is then a particular case of the march which the art of therapeutics follows in our school; it becomes less and less active; it attaches an always increasing importance to the simple action of the curative forces of nature. It is necessary to recognise truly that our predecessors were enterprising to a degree which terrifies us to-day. Every pleurisy, every pneumonia, was considered as the effect of an exaggerated plethora, and rendered legitimate the blood-lettings to which the death alone of the patient came to put an end. For the least wound of the head, they used to declare the cranium fractured, and to apply to see what would happen two or three trepans. If a patient had an attack of epilepsy, they declared him afflicted with cerebral congestion, and made his innocent blood run in waves. There was no case of keratitis, or ciliary blepharitis, which did not necessitate as a necessary accompaniment, a seton at the nape of the neck. For a simple fracture of the clavicle, they made the patient carry on his shoulders twelve graduated compresses, in a twenty-two metres of bandages. Each little child afflicted with Pott's disease found itself at the head of a regiment of cauteries, methodically arranged in two files, right and left, along its vertebral column.

We have become at the present day more sceptical. When it appears to us that the patient will cure himself, we give him every facility for obtaining that result. On the other hand, we are wrong perhaps to assist so often, as simple spectators, at the fatal march of pathological phenomena which the ancients would have sought to modify by violent and terrible procedures. Are we progressing? The future is the supreme judge which will, as a last resort, decide this question. For us, who live now, we have a more modest part to play; it consists in congratulating those practitioners who, by the success obtained in the treatment of doubtful and difficult maladies know how to work toward the perfection of our art. This is what we do now with regard to M. Hardy.

Medical News.

Royal College of Surgeons of England.—The following gentlemen, having passed the required examinations for the diploma, were duly admitted Members of the College at meetings of the Court of Examiners on the 25th and 26th ults.:

Bethell, Alfred, L.S.A., Pilton, Somerset.
Bland. George, L.S.A., Gerrard street, Islington.
Cartwright, Henry Gordon, Burton-on-Trent.
Cawley, Thomas, Great Yarmouth.
Fordham, John William, L.R.C.P. Edin., Stepney.
Foster, William James, Birmingham.
Griffith, Richard Glyn, Bangor, North Wales.
Hamilton, Alexander, M. S., M.D., Queen's Univ. Irel. Ballymoney, Co. Antrim.
Magrath, John, L.S.A., Forest row, East Grinstead.
Matcham, Alfred, L.R.C.P. Edin., Lowestoft.
Moore, Arthur Jackson, L.S.A., Debenham, Suffolk.
Murdoch, Donald. L.S.A., Rotherhithe.
Newman, Alfred Kingcombe, Hawk's Bay, New Zealand.
Oldham, Charles Edmund, B.A. Cantab., Cambridge.
Pitt, Isaac, L.R.C.P. Edin., Birmingham.
Palmer, Ambrose Myrie, Clapham.
Popham, Francis W. H., L.S.A., Gawler, South Australia.
Bendall, William, L.S.A., Maiden Newtown, Dorchester.
Ross, W. Graham, M.D. M'Gill Coll. Montreal, Ontario, Canada.
Russell, Ebenezer Geer, L.S.A., Pool, Cornwall.
Skaife, Frederick, L.R.C.P. Edin., Easingwold, Yorks.
Steele, Edward Henry, L.S.A., Dorchester.
Stokes, Henry Haldane, M.B. Dub, Tralee, Co. Kerry.
Wade, Reginald, L.S.A., Cross, Somersetshire.
Wallace, Thomas, M.D., Queen's Univ. Irel., Cardiff.
Ward, Walter Alfred, L.S.A., Notting hill.
Weatherhead, John Fraser, L.S.A., Holloway.
Williams, Alfred Henry, M.B. Aberd., Brixton.

The Geography of Disease.—The first of a weekly series of six lectures on the Geographical Distribution of Disease in England and Wales, was delivered on Thursday evening in the theatre of St. Thomas's Hospital, by Mr. Alfred Haviland, whose careful mapping-out of the comparative local prevalence of dropsy and heart-disease has attracted much notice, and will now be followed by a similar system of charts and investigations of typhoid fever, cancer, phthisis, and scrofula, concluding with a summary of the geographical distribution of health. After a general introduction, Mr. Haviland entered upon the theme which is designed to occupy, more minutely, the space of his second lecture, namely, Typhoid Fever. He drew the necessary though often overlooked distinction between this disease and typhus, showing how the two maladies differ in all their most characteristic phenonema. With regard to the preventibility of typhoid fever—a modern doctrine to which he gave his qualified acquiescence—the lecturer remarked on the lamentably slow advance of practical instruction on the subject. True typhus fever, Mr. Haviland observed, is peculiar to crowded towns. Typhoid exists in rural districts as well as in towns; co-exists with typhus, it may be; but is distinct from and independent of that disease. Pointing to the coloured divisions of maps, Mr. Haviland showed to what extent typhoid fever follows the conditions of physical geography; and at the same time took care to remark how far the disease might be attributed to social rather than geological causes.

The late Dr. Baird, of the British Museum.—In losing Dr. Baird, F.R.S., F.L.S., the British Museum has lost one of the most valuable members of its staff. Dr. Baird, who was born in Scotland in 1803, was educated at Edinburgh, Dublin, and Paris, for the medical profession, and served for some years as a surgeon in the naval service of the late East India Company. His voyages in this capacity gave him ample opportunities for the study of his favourite pursuit—zoology. In 1841 he accepted an appointment in the Zoological department of the British Museum, and this he retained up to the time of his death, which occurred on Saturday last, after a protracted illness. His leisure hours were often devoted to the employment of his pen upon the various branches of natural history. His writings are chiefly to be found in periodicals: but his most important work was a "Natural History of the British Entomostracæ," which was published under the auspices of the Royal Society in 1850. Subsequently Dr. Baird was elected a Fellow of the Royal Society. In private life he was greatly beloved on account of the unvarying amiability of his disposition and the kindness of his manners.—*Standard.*

Small-pox in Philadelphia.—A correspondent of a morning paper says that, small-pox of a very malignant type has been prevailing for many weeks, and still prevails, in Philadelphia, to an extent that makes that city shunned by travellers, and greatly injures its trade. It was the small-pox that deterred Nilsson from singing in Italian Opera to the Philadelphians upon the close of the opera season in New York. The malady was at one time so fatal and wide-spread that the deaths from it constituted one-fourth of the entire weekly mortality of the city. The number had fallen, however, last week from 260 to 216, and hopes are entertained that it will soon disappear. In New York there has been during the winter a constantly-increasing number of deaths from small-pox every week, but nothing like the alarm inspired by it in Philadelphia has yet been felt, nor is the disease itself of so virulent a character. The Board of Health is hard at work vaccinating the poorer classes of citizens, and endeavouring to get the richer class to be re-vaccinated, as the only means of checking the progress of this scourge.

◆

Veratrum Viride as an Arterial Sedative.

Dr. John S. Wilson states: (*Atlanta Med. Jour.*) "Veratrum is one of the few drugs in the administration of which we can have the unerring guide of figures as to the regulation of the dose. And so uniform and certain is its sedative action, that we can confidently predicate our directions on this result. Therefore, all we have to do in the administration of the remedy is to begin with a minimum dose and gradually increase until the desired reduction of the pulse is accomplished, as counted by the watch. My practice has been to begin with two or three drops Norwood's Tincture for an adult, repeated every three hours, increasing one drop each dose until the pulse is reduced to the normal standard. When this is attained, I diminish the dose to one drop, and discontinue, if the pulse sinks below the point mentioned. By pursuing this course, I have succeeded in effecting the desired sedation in almost all cases, without nausea, vomiting or other disagreeable symptoms."

Uterine Tumour in Child One Year Old.

Dr. P. J. Farnsworth details a case in the *Medical and Surgical Reporter*, of a child a year old, afflicted with a uterine tumour. He diagnosed it as a polypoid tumour of the gelatinoid variety, attached to the neck of the uterus. The tumour grew rapidly as it was removed, so that the operation had to be repeated. The fourth removal was by the écraseur, after which the little patient sank and died on the third day. It was believed that she died of metro-peritonitis, as she was the very picture of health up to the day of the last operation. The doctor had never seen the record of such a case, a uterine tumour in a child little over a year old, reappearing only after the manner of nasal polypi.

NOTICES TO CORRESPONDENTS.

A Correspondent says: When the question of a baronetcy for the Surgical Profession in Ireland has been mooted in the Medical Press, it would seem but just that the prior claim of Edinburgh should not be forgotten. Comparisons are said to be invidious, yet (as names have been brought forward) I suppose it will generally be conceded that in Syme, Fergusson, Liston, and Miller, Edinburgh has produced surgeons of a higher repute than any who have emanated from the Dublin school. Moreover, as far as I am aware, a baronetcy has not been conferred upon any surgeon practising in Scotland during the present century. It is, therefore, to be hoped that the Profession in the Northern Capital may not be any longer ignored in the distribution of merited honours.

Syphilitic Inoculation.—A Correspondent who takes great interest in this subject, asks us if we know of instances in which the theory recently propounded in our columns by Dr. Morgan, and since advocated in his work "On the Contagious Diseases," has been tried; or the experiments as to vaginal discharge repeated in other quarters, and with what results? The whole question being of such vast importance to the Profession and the public at large, we shall be pleased to receive and compare notes on the subject from any of our readers.

Mr. Sloane, East Grinstead.—You will find the name in the Pass List of the Royal College of Surgeons, in the news column of our present number.

BOOKS, PAMPHLETS, and MEDICAL JOURNALS RECEIVED.

A Text-Book of Pathological Histology. Translated from the German of Dr. Rindfleisch, by Drs. Kloman and Miles. Philadelphia.

"Suggestions for a Ready Method of Recording Surgical Cases in Hospital Practice."

On Antisepticity in Surgery. Two Pamphlets by Edward Lund, F.R.C.S. Manchester: J. E. Cornish.

Worms: A Series of Lectures on Practical Helminthology. By T. Spencer Cobbold, M.D. London: J. and A. Churchill.

Monthly Microscopical Journal; Hardwicke's Science Gossip; Nature; British Journal of Dental Science; The American Practitioner; Allgemeine Wiener Medizinische Zeitung; The British Pharmacist; Boston Medical Journal; La France Medicale; The American Chemist; The Public Ledger Almanac, &c.

VACANCIES.

Township of Manchester. Senior Resident Surgeon to the Workhouse Hospital. Salary £300 per annum.

Kent Hospital, Canterbury. Assistant Surgeon. Salary £50.

Salford Union. Assistant Medical Officer. Increasing salary, commencing at £130, with residence.

Newark Hospital. Resident Medical Officer. Salary £100, with board.

Weston-Super-Mare Hospital. House-Surgeon. Salary £60, with board and residence.

Royal Sea Bathing Infirmary, Margate. Resident Surgeon. Salary £100, with board.

Nottingham General Hospital. Assistant House-Surgeon. Salary £80.

Mile-end Union. Medical Officer. Salary £200 per annum.

County of Meath Infirmary. Apothecary. Salary £52 per annum, with residence. (See advt.)

Clane Dispensary District of the Naas Union. Medical Officer. Salary £100 per annum, exclusive of fees. (See advt.)

MEETINGS OF THE LONDON SOCIETIES.

Wednesday, Feb. 7.—Royal College of Surgeons of England, 4 p.m. Professor Erasmus Wilson, "On Dermatology."

Hunterian Society.—7 p.m. Annual Meeting for Election of Officers. —8 p.m. Annual Oration, by Dr. Hughlings Jackson.

Obstetrical Society of London.—8 p.m. Annual Meeting.—Dr. Phillips, "On Retroflexion of the Uterus as a frequent Cause of Abortion."—Dr. Bantock, "On the Use of the Sponge Tent in Menorrhagia."—And other papers.

Thursday, Feb. 8.—Royal Institution, 3 p.m. Prof. Odling, "On the Chemistry of Alkalies and Alkali Manufacture."

Friday, Feb. 9.—Royal College of Surgeons of England, 4 p.m. Prof. Erasmus Wilson, "On Dermatology."

Clinical Society of London.—8½ p.m. Adjourned Discussion on Mr. Cooper Forster's paper, "On the Treatment of Popliteal Aneurism." —Mr. Hulke, "On the Therapeutic Value of Condurango as a reputed Cure for Cancer."—Mr. De Morgan: A supplemental paper on the same subject.—Mr Bryant, "On Two Cases of Recto-Vesical Fistula successfully treated by Colotomy."

Royal Institution, 9 p.m. Prof. Humphry, "On Sleep."

Saturday, Feb. 10.—Royal Institution, 3 p.m. Mr. Wm. B. Donné, "On the Theatre in Shakespeare's Time."

Monday, Feb. 12.—Medical Society, 8 p.m. Ordinary Meeting.

Tuesday, Feb. 13.—Royal Institution, 3 p.m. Prof. Rutherford, "On the Nervous and Circulatory Systems."

Royal Medico-Chirurgical Society, 7.30. Election of new Members by Ballot.

Wednesday, Feb. 14.—Epidemiological Society, 8 p.m. Dr. J. N. Radcliffe, "On the Recent Diffusion of Cholera in Europe."

OPERATION DAYS AT THE LONDON HOSPITALS.

Wednesday, Feb. 7.

APPOINTMENTS.

Carter, R. C., L.R.C.S.I., Medical Officer for the Kilcullen Dispensary District of the Naas Union, Co. Kildare.

Connolly, P., L.K.Q.C.P.I., Medical Officer, &c., for the Multyfarnham Dispensary District of the Mullingar Union, Co. Westmeath.

Fleetwood, W. J., L.R.C.S.I., L.K.Q.C.P.I., Visiting Surgeon to the General Infirmary, Chester.

Jardine, J. B., M.D., Medical Officer of Health for Chatham.

Kelly, R. W., L.K.Q.C.P.I., L.R.C.S.I., Medical Officer, &c., for the Ballindine District of the Claremorris Union, Co. Mayo.

Marshall, J., L.R.C.P.L., Assistant Visiting Surgeon for Canterbury and Dover, under the Contagious Diseases Acts (Women).

O'Connor, A. D., M.D., Medical Officer, &c., for the Blackrock Subdistrict of the Cork Dispensary District, Cork Union.

O'Sullivan, S., M.D., Medical Officer, &c., for the Bishopstown Subdistrict of the Cork Dispensary District, Cork Union.

Strathy, F. R. L., M.D., L.R.C.P.Ed., Resident Physician to the Royal Hospital for Sick Children, Edinburgh.

Sweenie, W. F., M.B., L.R.C.S.Ed., Medical Officer for the Killea Dispensary District of the Londonderry Union.

Army Medical Department.—Assistant Surgeon W. S. Oliver, M.D., from the 60th Foot, to be Staff-Surgeon, vice Alfred Hooper, placed upon half-pay.

Assistant Surgeon J. H. Hughes, M.D., from the 38th Foot, to be Staff Assistant Surgeon, vice W. G. Martelli, appointed to the 60th Foot.

Marriages.

Lacey—Kirbell.—On the 31st ult., at St. Michael's Church, Chenies, Bucks, Thomas Warner Lacey, L.R.C.P.L., M.R.C.S.E., of Plumstead, Kent, to Sarah Anne (Daisy), youngest daughter of Mr. Edward Kirbell, of The Dell, Latimer, Bucks.

Madras—Gillman.—On the 28th Dec., 1871, at Majourney Church, by the Rev. John Madras, assisted by the Rev. Edward Spring, Robert Conner Madras, M.D., Bilgoumy Villa, son of the late Rev. John Madras, Vicar of Aglist, to Eliza Bennett Gillman, youngest daughter of Herbert Gillman, Esq., of Cloutradmore.

Margary—Monro.—On the 1st inst., at Stoke Church, Devonport, Arabel Sophia, second daughter of P. J. Margary, Esq., to Edward William, second son of Henry Monro, Esq., M.D., of Cavendish square, London.

Walker—Rougier.—On the 30th ult., at St. John's Church, Lancaster, Samuel Walker, M.R.C.S.E., of Middlesbro'-on-Tees, to Emily Tymms, second daughter of the late Wm. Rougier, Esq., of York.

Deaths.

Baird.—On the 27th ult., at Burlington road, Westbourne park, Wm. Baird, M.D., F.R.S., of the British Museum, aged 69.

Day.—On the 31st ult., at Andersey, Torquay, George Edward Day, M.D., F.R.C.P., F.R.S., late Chandos Professor of Medicine in the University of St. Andrews, aged 56.

Lampard.—On the 30th ult., Jacob Lampard, M.R.C.S.E., of Neyland, South Wales, aged 67.

St. John.—On the 1st inst., at Maryland road, London, Charles St. John, M.R.C.S., aged 33.

FIRST-CLASS PRACTICE FOR SALE.—Price £400. Average nett income, £700.—In consequence of the retirement of the present incumbent, who has been in the practice upwards of 30 years, a very exceptionally good opening occurs. The practice is situate in the North-east of England in a first-class farming and agricultural district, with good fees, &c. For particulars apply to A. A. T., care of Messrs. Baillière and Co., Publishers, 20 King William street, Strand, London.

COUNTY OF MEATH INFIRMARY.

WANTED a properly qualified

APOTHECARY, who will also have to act as SECRETARY and REGISTRAR, and keep the Books and Accounts; he will probably be required to reside in the house. Salary £53 a year, with furnished apartments, coals and candles.

The Election will take place at Navan, in the Board-room of the Infirmary, on WEDNESDAY, February 14, at One o'clock, P.M. A personal attendance will be required. Testimonials, or copies of them, to be lodged with T. FITZHERBERT, Esq., Blackcastle, Navan (if by post prepaid) on or before Wednesday, February 7th.

NAAS UNION.

CLANE AND TIMAHOE NORTH DISPENSARY DISTRICT.

MEDICAL OFFICER WANTED.—The Committee of Management of the above District will, at their usual Monthly Meeting to be held at the Dispensary, Clane, on MONDAY the 5th FEBRUARY, at Twelve o'clock (the late Medical Officer having resigned), proceed to appoint a Medical Officer for the District, at a Salary of One Hundred Pounds per annum, exclusive of Vaccination Fees.

The person to be appointed must possess the qualifications required by the Poor-law Commissioners and to reside in the District.

Applications and Testimonials will be received by me up to Eleven o'clock on the day of election, and Candidates to be in attendance on that day.

RICHARD WILSON, Hon. Sec.

Prosperous, January 25, 1872.

PUBLIC SCHOOL EDUCATION IN IRELAND.

COLLEGE OF ST. COLUMBA, COUNTY DUBLIN.

VISITOR: THE LORD PRIMATE.

The College is intended for the Education of the Sons of the Nobility, Clergy, and Gentry, from the age of nine years and upwards. The course of instruction is similar to that of the great Public Schools in England, in which Classical Studies are made the chief foundation. Particular attention is also paid to Mathematics and English. French, German, Drawing, and Vocal Music are also included.

Boys are prepared for the Universities of Dublin, Oxford, and Cambridge; and to a considerable extent for the Military and Civil Service.

Terms—*Sixty Guineas*, inclusive.

There are Two Exhibitions attached to the School, tenable in the University of Dublin, worth £20 to £30 a year.

Applications should be made to the Rev. the WARDEN.

The Christmas Vacation ends on January 25th.

COOKESTOWN HOUSE, INSTITUTED FOR

THE MEDICAL TREATMENT OF THE INSANE OF BOTH SEXES.

This highly respectable Mansion in no respect resembles, either internally or externally, what is usually known as an Asylum.

The Demesne, Conservatories, Graperies, and Grounds are unusually extensive, and in good condition.

There are Billiard Tables for both sexes, with indoor and outdoor amusements, including Vehicles.

Cookestown House is within three miles of Carrick-on-Suir Station, with a like distance from Fiddown, both on the Waterford and Limerick Lines, and in connection with the G. S. & W. and Kilkenny Lines.

For terms, and Form of Admission, apply to the Resident Physician.

JOHN PEPPARD, M.D., &c.
Cokestown House, Piltown, co. Kilkenny.

OXYGEN.

BARTH'S NEW PORTABLE APPARATUS

WITH CONDENSED GAS.

See "MEDICAL PRESS AND CIRCULAR," of *July 19th*, 1871.

Price £4 4s. 0d. complete.

A LIBERAL ALLOWANCE TO THE PROFESSION.

GEORGE BARTH AND Co.,
26 DUKE STREET, NEW OXFORD STREET,
LONDON, W.C.

May be had on hire.

Established 1848.

PROFESSIONAL AGENCY AND MEDICAL TRANSFER OFFICE.

50 LINCOLN'S INN FIELDS, W.C.

J. BAXTER LANGLEY LL.D. M.R.C.S., F.L.S.,

&c., (KING'S COLL.), and Author of VIA MEDICA,

Has always upon his books a large number of desirable investments and available Appointments for negociation.

The business of the Professional Agency is based upon the general principle that no charge is made unless work has been done and services rendered.

No Commission charged to Purchasers.

Full information as to terms, &c., sent free on application.

Office hours, from 11 till 4; Saturdays excepted.

PRACTICES AND PARTNERSHIPS NOW OPEN for negociation (in addition to those advertised in Dr. Langley's List, (which is sent post free on application).

Y 888. MIDLAND. In a small town in a well-populated district where there is an unusually favourable opening. Receipts upwards of £400 a year; appointments to the value of £100 a year can be at once secured; house contains twelve rooms, with stable and garden. Can be let or sold.

Y 895. DEATH VACANCY. In a pleasant country town, the succession to a practice which realised about £500 a year, though the income has recently declined, the connection affords an excellent introduction. There is a convenient residence at a low rent; easy terms would be conceded to an immediate purchaser.

Y 894. Within 100 miles of LONDON, with easy access by rail, a well-established first-class Country Practice, realising £500 a year, but capable of increase to double that amount; no opposition within four miles; appointments £240 a year, could be transferred to a suitable successor. There is a very convenient residence, with detached surgery, &c. Rent £30. An efficient introduction can be guaranteed.

Y 891. The LEADING PRACTICE in a large and prosperous town in the Midland Counties. The connexion is old-established, and includes the best residents in the locality. The receipts have averaged for many years £1,000, but during the last year have declined somewhat, in consequence of the ill health of the incumbent, which is the cause of transfer. The appointments yield upwards of £400 a year, and it is believed can be transferred without difficulty to a suitable successor. The usual midwifery fees are £2 and £3 3s., those at lower rates attended by the assistant. The residence is situate in the best part of the town; is large and commodious, with extensive garden, greenhouse, and groom's cottage. Rent of the whole £70. A most efficient introduction can be given.

Y 886. Old ESTABLISHED PRACTICE in the suburbs of a large manufacturing town in the West Riding of Yorkshire. Receipts £600 a year; appointments £100; one horse does the work, the practice lying within a radius of 3 miles; a good introduction can be given. The whole for immediate disposal.

Y 897. Within 20 miles of LONDON with easy access by road and rail, a well established PRACTICE, realising upwards of £450 a year, and capable of great increase. Appointments yield £100 a year; no opposition within three miles; considerable building is going on in the neighbourhood. The house contains ten rooms, with garden and stabling, orchard, &c. Rent £40; terms moderate.

Y 896. FIRST CLASS PARTNERSHIP in a town and country practice, carried on for many years past by the present incumbent. Average receipts for last three year, £1,350; last year, £1,450. There is no dispensing; patients include the best residents in the locality; a third share for disposal for £950 with provision for succession to the one-half at an early date, and the reversion of the whole at the end of the term of partnership.

Dr. Langley's Quarterly List of selected Practices and Partnerships for January is now ready, post free on application.

LECTURES ON DERMATOLOGY.

Delivered in the Royal College of Surgeons of England, in February, 1872, by

Erasmus Wilson, F.R.S.,
Professor of Dermatology to the Royal College of Surgeons of England.

Lecture I.

Mr. President and Gentlemen,—In approaching a subject of study of whatever kind, it is important that we should make ourselves acquainted with its bearings and landmarks. And, applying this principle of reasoning to the study of the cutaneous investment of mankind, we shall find that the principal points of that organ to be considered are,—

The cutis vera,
Epidermis,
Follicles,
Hair, and
Glands;

To which may be added two principal functions of the organ, namely,—

Nutrition, and
Secretion.

In the diagnosis of the state of the skin, it is necessary, therefore, to investigate these separate parts and functions, and if any abnormal condition present itself in either, the discovery of such aberration will constitute the basis of the pathology of the skin, and we may thereupon be led to conclude that the disorder is one of the skin proper, or cutis vera; of the epidermis, that is, the epithelium of the skin; the follicles; the hair; the sebiparous, or sudoriparous glands; or of the function of nutrition or sensation.

In a compound organ like the skin, made up of mutually co-operative and mutually dependent parts, it is a rule, almost without exception, that several of the component structures will be involved in any abnormal process that may be in action. For example, in common inflammation of the skin, the epidermis and follicles will suffer as well as the cutis vera, but it is evident in that case that the affection of the epidermis and of the follicles will be subservient or secondary to the inflammation of the cutis vera, and may, therefore be lightly regarded in forming our diagnosis. Diagnosis, in fact, should determine, not only the essential and primary aberration from the normal standard, but must distinguish also that which is secondary and of comparatively little importance.

If we turn from the anatomical and physiological consideration of the skin to its abnormal or pathological condition we shall find that it is liable to—

Common inflammation,
Specific inflammation,
Aberration of nutrition, and
Aberration of sensation.

These *four* heads are the basis of arrangement of subject, or classification, which I have adopted for the present lectures, and for the disposition of the objects constituting the dermatological collection in the College museum; whilst, as a matter of convenience, I have appended to these primary groups the special function of pigmentation and disorders of the epidermis, nails, hair, and glands, thus:—

Aberrations of Pigment,
Diseases of Epidermis and Nails,
Diseases of Hair,
Diseases of the Glands.

The diseases of *common inflammation* of the skin are typified by—eczema and scabies, affections of the cutis vera, lichen and impetigo, affections of the follicles, erythema, pemphigus, furunculus, and traumatic affections.

The diseases of *specific inflammation* are,—the eruptions accompanying the exanthematous fevers, namely, rubeola, scarlatina, and variola, the cutaneous manifestations of syphilis, and the cutaneous manifestations of elephantiasis.

The diseases of *aberration of nutrition* constitute a large and important group, beginning with lepra, lupus, and epithelioma, and embracing trophic changes of the skin and its different constituents; for example, the epidermis, rete mucosum, papillæ cutis, vessels, fibrous tissues, and cell-tissues.

The diseases of *aberration of sensation* are pruritus and prurigo.

Finally, although all the remaining diseases might have been treated of under the four general heads already stated, a certain practical advantage is obtained from considering them in separate groups; for example:—

Aberrations of pigment; diseases of epidermis and nails; diseases of hair; and diseases of the glands of the skin, sebiparous and sudoriparous.

My *first* and inaugural course of lectures in 1870 was devoted to a brief definition of the different diseases of the skin, and the construction of a framework or arrangement which should accommodate and find place for every member of the family, however insignificant; in a word, a synopsis of affections of the skin.

In my *second* course I commenced the more exact description of these affections, beginning with "Diseases of common inflammation," and directing my attention especially to eczema and its allies, namely, scabies, lichen, and impetigo.

The summary of my treatment of this subject was to the effect,—

1. That eczema is an example of common inflammation of the skin.
2. That the inflammation of eczema differs in no respect from inflammation of other organs of the body.
3. That if any apparent differences be presented to the observation, such apparent differences will be found to arise out of the configuration and situation of the organ.
4. That the variety of appearance of eczema is due to the composite structure of the skin, and to the modification of the organ by age, vital power and idiosyncracy.
5. That as a corollary to these data, eczema requires the therapeutical treatment that is applicable to every other surgical affection attended with inflammation.

Our dermatological collection is comparatively rich in objects representing eczema, of which eighty-six will be found in the catalogue; and included in this number there occur illustrations of eczema in its manifold forms; in its dry and in its moist form; eczema in which a general redness or erythema is the predominant character; eczema with congested and uplifted follicles, giving rise to pimples; eczema with vesicles; eczema with copious exudation; eczema with hypertrophy and desquamation of the cuticle; eczema with hypertrophy of the tissues of the integument and of the limb; eczema with hypertrophy of the nails, and eczema of the mucous membrane with hypertrophy of the epithelium. Of the number, eighty-six, thirteen are models constructed by my amiable and accomplished friend, M. Baretta, and to this number two others have been added since I had the honour of addressing you, Sir, and the Fellows and Members of this College, in this theatre, at the beginning of the past year.

Model 514 is an example of chronic eczema affecting the hands, front and back, the skin is inflamed, indurated, and fissured, and the epidermis thickened by hypertrophy. The fissures are produced by stretching the indurated and brittle integument, and are chiefly met with in the lines of motion, and the hypertrophy of the epidermis is consequent passive congestion of the vessels of the skin.

Model 515, is another example of chronic eczema, affecting the the front and back of the hand, with fission, hypertrophy of the epidermis and desquamation. Hypertrophy of the epidermis of the tips of the fingers has given rise in the left hand to displacement and thickening of the nails, or onychogryphosis. Both hands also present a number of large papules, which are conical on the back of the hand, and flattened in the palm. Scratching shows the papules to be solid in structure and exudative. On the back of the hand they are surmounted with a thick epidermic crust, while in the palm they are prevented from rising by the normally thick epidermis of that region. The eruption began in the form of pruriginous papulæ, and reached its present state in a fortnight, and subsequently got well without other treatment than water-dressing and baths.

Another addition which has been made to the eczematous group within the same period is No. 516, a model representing the leg, and exhibiting one of the forms of lichen planus. The eruption is aggregated; a few scattered papulæ may be seen around its circumference, but it is chiefly remarkable for its purple colour and brown pigmentation. The morbid surface is corrugated and papulous, and bears evidence of a chronic history, while an oozing spot at its upper and front margin is indicative of pruritus, and the consequence of scratching with the nails. Wherever the papulæ have subsided, a deep pigmentary stain is left behind; and the purple hue of the whole eruption must be referred to prolonged congestion and chronic dilatation of the capillary vessels.

The term "lichen" has undergone considerable modification of meaning since it was first made use of by the Fathers of Medicine. By them it would seem to have been applied to a circular blotch of eruption, possibly to a lamina of altered epidermis, which gave the idea of being stuck on the skin, as we might stick a wafer to its surface by *licking* the wafer with the tongue. Thus there may have been red lichens and white lichens, the latter, no doubt, being represented by lepra, the so-called psoriasis of certain writers subsequent to the period of Willan. And it is deserving of remembrance that the term "lichen" was borrowed by the naturalists from the physicians, and was conferred by them at second hand on the cutaneous growths which are met with so commonly on the bark of trees.

By Willan, however, and at the present day, lichen is the term used to distinguish pimples, some writers including under this name every kind of papular prominence of the skin, and others, with myself, limiting its use to those that result from inflammation of the follicles. It is in this latter sense that the pimples on the model before us are termed lichen; and it is in consequence of their flatness, the depression of their surface, and the smooth horn-like polish of their summit, that I have termed the eruption "lichen planus." Each pimple presents also in its centre the appearance of umbilication, resulting from its perforation by the follicle, and not unfrequently the aperture of the follicle is distended, and, as it were, choked with exuviated epithelium and desiccated sebaceous substance. When the papulæ are rendered confluent by the inflammation and thickening of a broader extent of integument, they exhibit the appearance which is presented on the model. Their colour when isolated, or in small clusters, is a dull purplish red, but in their aggregated form they constitute blotches, which are covered over for the greater part of their extent by a ragged desquamation, consisting of epithelial exuviæ and disintegrated epidermis.

In determining the *diagnosis* of a cutaneous disease, we recognise a general or distant appearance, and a particular or closer aspect; the essential characteristic of the eczematous family is a complication of appearances, a mingling together of several of those states of the morbid skin, which are termed "lesions." For example, there is redness, there is papulation, sometimes there are minute vesicles, sometimes pustules, then there is exudation in its moist and running or encrusted stage, and desquamation. Again, there is swelling to a slight degree, and more or less induration of the skin; and in very chronic cases there is hypertrophy of the tissues of the skin, extending more or less deeply. The *plus* or the *minus* of these lesions we endeavour to distinguish by the terms—erythematous, papulous, vesiculous, pustulous, ichorous, squamous, and so forth; by which terms we have no intention of implying a different kind, but simply a difference of manifestation of eczema. Sometimes the cases are so markedly papulous that we employ the term lichen; and sometimes the eruption is specially distinguished by purulent vesicles, and then we use the term impetigo. Nor must the student of dermatology be surprised when, after a further insight into the phenomena of this protean affection, he discovers such terms as lichenous eczema, and impetiginous eczema or eczema impetiginodes.

A correct appreciation of eczema helps us very much to the diagnosis of other cutaneous affections, and particularly so does the absence of the multiple manifestation which is so specially characteristic of that disease. It is thus that at a glance we are enabled to differentiate erythema, pemphigus, and furunculus, the three forms of disease which next claim our attention.

ERYTHEMA.

The essential characteristic of erythema is—hyperæmic redness; it is typified by a blush, and may be termed a pathological blush. It not only very commonly appears like a blush, but it as commonly passes away like a blush, leaving behind it no trace of injury to the skin, and no vestige of its existence. The local pathology of an erythema is identically the same in all its varieties, a vascular congestion of the tissues of the skin determined by paresis of the vaso-motor nerves; but the cause of the affection may be various—it may be internal or constitutional, or it may be local. Nevertheless, the surgical aphorism of treatment, "remove the cause," remains precisely the same. Comparing erythema with eczema, we might venture to say that eczema is a state of hyperæmia of the skin, with a breach of its continuity, whereas erythema is hyperæmia without breach of continuity. Nevertheless, erythema is sometimes accompanied or followed by desquamation, and sometimes as in erysipelas, which is an aggravated erythema, by vesication, as well as by desquamation.

The members of the erythematous group, the erythematous affections, are three in number, namely:—

Erythema,
Erysipelas, and
Urticaria.

These affections are characterised by the possession of certain features in common, for example,—a bright tint of redness, more or less swelling, more or less itching, and more or less mobility or change of position. If the redness be general in its distribution, and apparently superficial, or if it be partial and at the same time superficial and with only slight swelling, we may be sure that the case is one of *erythema*. If, on the other hand, the redness being the same, there is a manifest swelling with infiltration and œdema, a sense of depth of penetration of the skin, and if, furthermore, the skin relieves itself of its inward tension by effusion and vesication on the surface, the case is one of *erysipelas*. But if, on the other hand, the most striking symptoms of the case be itching and evanescence, the case is named after a similar affection produced by the irritation of the nettle on the skin, namely, *urticaria*. In the fewest possible words I may define erythema to be redness without swelling; erysipelas as redness with infiltration and vesication; and urticaria as redness with slight elevations of a white colour produced, to all appearance, by a state of muscular spasm of limited districts of the skin.

The erythematous family brings to our notice very strongly certain pathological phenomena of the skin which are deserving of more than passing attention; for example, there is the *fugitive* character evinced by suddenness of appearance and disappearance; secondly, there is the *migratory* character, as shown by the wandering propensities of the affection; and thirdly, there is the *tumescent* character, which is equally remarkable. These phenomena are all of a neurotic character, a state of temporary relaxation of nerve-force gives rise to distension of the capillaries as represented by hyperæmia; while nervous tension, by inducing contraction of the capillaries, restores the equilibrium of the circulation, or in a greater degree, produces pallor of the skin. The blush and emotional paleness of the surface are physiological illustrations of these phenomena, which are repeated with greater force and severity, pathologically, in that example of erythema termed "erythema fugax," in the occasional recession or retrocession of erysipelas, and very manifestly in urticaria. Erythema fugax is a form of the affection excited by emotion, and very commonly, as a reflex phenomenon, by the stimulation of the gastric plexus of the pneumogastric nerve, and is developed on the face, neck, or chest; it may last for a few hours or for a few days, and it may recur at uncertain periods, very often, daily. This form of erythema contrasts very forcibly with the redness produced by contact and attrition of contiguous surfaces of the skin, with the erythema excited by irritants, and especially with the erythema of heat or cold; the latter being exemplified by common chilblain.

The *migration* of the erythematous affection is due to a propagation of the nervous impulse or shock, and consequent hyperæmia, to the neighbouring part of the skin, sometimes by continuous and sometimes by centrifugal progression. Continuous migration is illustrated by the wandering propensities of erysipelas; and centrifugal migration by the annulate forms of the affection termed erythema annulatum, circinatum, gyratum, marginatum, and iris, forms in which the spot first attacked is rapidly forsaken, and the hyperæmia moves like a wave to a distance, still preserving its annulate figure; and the same phenomenon is also seen not unfrequently in urticaria.

The *tumescence* of the erythematous affections is a consequence of exudation from the capillaries into the cell tissues, giving rise to prominence in a greater or less degree, and appearing often with remarkable suddenness. It is in this manner that we explain the smaller prominences termed erythema papulosum, tuberosum, and nodosum, which are varieties differing only in degree, and the sudden and occasionally massive swellings of erythema tumescent, as also the dense and sometimes brawn-like thickening of erysipelas. The wheals of urticaria have likewise been attributed to exudation, but their rapidity of formation in certain instances seems to point to muscular spasm for their production, as, for example, when they spring up in the course of pressure with a pencil, tracing figures on the skin.

The exudation from the capillaries in the erythematous affections, after being detained in the tissues for awhile, is usually absorbed, leaving scarcely a vestige of its existence behind; but in one of the forms of erysipelas the exudation finds its way to the surface, lifting up the horny epidermis into vesicles or blebs. The precise character of the exudation also presents certain varieties, being more plastic in some instances than in others, and more or less impregnated with the colouring elements of the blood. Very commonly the prominences of erythema leave behind them yellow and purplish stains in the skin, and in one form of erythema, namely, in *purpura*, there is an absolute escape into the tissues through the capillary vessels of the red colouring matter of the blood.

Another phenomenon which accompanies the erythemata and is most conspicuous in urticaria, is *pruritus*. In fact, it is from this symptom, as much as from the development of white studs and wheals, that urticaria derives its name. The pruritus is present in different degrees, which are termed tickling, burning, and tingling, the pruritus of urticaria being of the latter kind. In some of the erythemata there may be no sensation beyond heat; in others there is heat with itching; and in others again a shooting pain that seems to appertain to vertical fibrillæ of nerves.

The examples of erythema in our collection are at present limited to erythema and urticaria. Among the former, we have the prominent varieties of the eruption assuming the appearance of papules, *erythema papulosum*, and protuberances, as in the instance of erythema *tuberosum* and erythema *nodosum*. Constitutionally, these forms are all due to disordered function, principally of digestion and assimilation. Nos. 86 to 92 are examples of eczema papulosum; the eruption is developed chiefly on the joints —in this instance, on the elbows and dorsum of the hands, and the size of the papulæ ranges from one and two lines to a quarter of an inch. Some of the papulæ have grown by the extension of their circumference to the breadth of half an inch, and one to a breadth of three quarters of an inch. The eruption was consequent on indigestion, and was attended with a teazing pruritus, most considerable at night. It yielded quickly to mild aperients; and after their decline, the papules left behind them purple yellow stains, resembling bruises of the skin.

(*To be continued.*)

◆

ON THE USE OF THE BAVARIAN APPARATUS IN THE TREATMENT OF FRACTURES (a).

By Anthony H. Corley, M.D., Queen's Univ. Ireland, F.R.C.S.I., &c.

Some months ago I introduced to the notice of the Medical Profession in this Kingdom a new method of treating fractures of the long bones. Some of my hospital colleagues and many of my friends have adopted it since, and I have myself acquired much more experience in its use. In describing it I endeavoured to explain its mode of application clearly, and accompanied the description with a woodcut, intended to render it more easily understood. Whilst in the hands of myself and my colleagues its success has exceeded our most sanguine expectations, I have not had such encouraging reports from others, and as these less fortunate results may depend on imperfect application, I wish, Mr. President, to direct to it in a special manner the attention of your society, exhibiting all the appliances necessary, the mode of using them, and detailing some of the results which I have obtained.

I am satisfied in my own mind that an apparatus which enables us to dispense with the use of splints, which permits us to inspect daily, if necessary, the state of the fractured limb, and which allows the patient to escape the wearisome necessity of six or eight weeks unchanging "dorsal decubitus," must quickly, when properly understood, supersede for ordinary cases every other method of treatment.

The appliances are few and inexpensive. A yard of the cheapest flannel, a pound or so of plaster of Paris, a few large pins with their heads bent, and a piece of calico or common roller make the surgeon independent of the surgical-instrument maker. The flannel is cut into two rectangular pieces the length of the fractured bone, and broad enough to encircle the limb and to leave a margin. One is a little wider than the other. Placing the narrow one evenly over the other they are sewn together by longitudinal stitching down the mesial line. They now resemble two sheets of note paper stitched together at the fold, the outer a little larger than the inner.

Raising the fractured limb carefully the flannel is to be spread smoothly under it, taking care that the line of sewing corresponds to the posterior mesial line of the limb. The two ends of the inner sheet are now brought evenly over the limb and fastened together by means of the bent pins, leaving the two outer half sheets spread on the surface of the bed. By extension, counter-extension, and manipulation, exact coaptation is secured, and now the plaster, mixed to a proper consistence with water, is partly smeared and partly poured on. The two outer sheets of flannel are rapidly brought over the surface of the plaster (which is now caught on both sides between the inner and outer layers) and are held together at their margins till the plaster sets, taking care that the extension and counter-extension are kept steadily up during that period. The pins must now be taken out (and it is for this purpose that their heads are bent), the edges trimmed, a few turns of the roller, or this kind of bandage (the use of which I have learned from my senior colleague, Dr. Stapleton) now being applied, and the entire operation, which does not occupy ten minutes, is finished. Muscular spasm at once ceases, the patient acquires the power of shifting his position, and a steady equable lateral pressure is secured, adapted exactly to the shape and inequalities of the limb.

Should it be necessary to maintain any peculiar position, as in the treatment of Potts and Colles's fracture, the assistant holds the limb while the plaster is setting, and a firm rigid case is at once secured, exercising uniform pressure, incapable of slipping, and maintaining the fractured ends in steady apposition. But the most important advantage connected with this apparatus is the facility with which it may be taken off. Most plaster and starch bandages are not only troublesome to apply, but so difficult to remove, that there is a strong natural tendency on the part of the surgeon to leave them on, and trust that the bones are uniting properly. I believe I am not the only surgeon who has seen, when the bandages are cut, certain peculiar angles and curves in the limb that Nature never intended to be there. Again, there are certain fractures, as compound ones, &c., in treating which we must keep a portion of the limb in such a way as to be readily examined. In the Bavarian apparatus, when the bandages are loosened, the two opposite sides can be separated, like the bent covers of a book, the line of stitching (which prevents the running together of the plaster) acting like the back or hinge of the book, and allowing the limb to be exposed or to be taken out if necessary. If the swelling, usually present at first, diminish very much, the anterior edges can be trimmed so as to allow tightening, or the whole case may be taken off and lined with cotton. I have used it *immediately* after accidents, and the only cases where I should defer its application are those of fracture from direct violence where there is such contusion that even the most equable pressure would be contra-indicated. I have used it with success in fractured femurs, tibia, fibula, humerus, radius, ulna, as well as with Potts and Colles's fractures, and have seen it used equally successfully by my colleagues, Drs. Stapleton and Walshe. When I say that Dr. Stapleton stamps it with his approval, I may at once claim attention for it. It is however with special reference to its efficiency in the treatment of Potts' fracture, Colles's fracture, and fracture of the shafts of the femur, that I now wish to speak. Everyone knows the difficulty of treating the first of these very common accidents. I have tried Dupuytren's splint applied with care by myself, and have had the pleasure in a day or two of finding the splint slipped round to the back of the limb, a circumstance highly calculated to allow the fracture (to use the time-honoured witticism) to turn out remarkably well. I have used the same splint, placing the limb after its application in a box, and I have used the box alone, trusting to padding to keep the proper position. I have secured *tolerably* favourable results, but only by means of constant trouble, frequent re-adjustment, and exemplary patience. When the Bavarian apparatus is applied there is no further interference necessary, the patient can at once lie on his side and get up to sit in a chair in two or three days.

With Colles's fracture I have since my attention was directed to Gordon's splint by Mr. Porter's paper, used none other until recently, and am perfectly satisfied with its superiority over every method of treatment before adopted. I have, however, tried how the plaster apparatus would suit, and have every reason to be pleased with the result. In applying it in this fracture I place a pad of cotton over the dorsal prominence, and hold the hand strongly adducted till the plaster is set. In the two cases of fractured femur which I have treated in the last six months I have secured such admirable results, and with such comfort to the patient, that I shall dwell at some length on the accessories to its successful use. I have always been under the impression that if in this fracture the ends of the bone could be got fairly into apposition and *kept together* by equable lateral pressure, there would not be the great necessity for extension and counter-extension now presumed to exist. The long splint, which enforces a constant recumbent attitude, and the use of a perineal band, has been felt to be such an imperfect mode of treatment, that dozens of modifications of it have been proposed, of which a few trials have convinced surgeons that the proper apparatus is still a desideratum. Counter-extension by the perineal band is particularly objectionable from its pressure, from the irritation or even ulceration so likely to be produced, especially in children, and from its tendency in fractures high up to increase the deformity.

(a) Read before the Surgical Society. See discussion on page 141.

With the plaster apparatus the necessary lateral pressure is produced, and the only requisite afterwards is some means by which slight extension and counter-extension can be kept up, less I believe for the purpose of producing any effect at the fracture than for preventing the motions of the patient's body (which I freely allow) from disturbing the position of the fractured ends. Having adjusted the apparatus I apply two long strips of soap plaster to the opposite sides of the leg, uniting them in a loop below the foot; to this loop I fasten a cord, which passes over the foot-rail of the bed, and has a weight dependant. This is the extension. I then raise the lower end of the mattress so that the feet are considerably higher than the pelvis, and the body forms the counter-extension. After the second day I found in both my cases that the patient could sit up to eat his dinner, &c., without pain increasing or disturbing his limb in the slightest degree.

My second case is still under treatment, and through the courtesy of my colleague, Dr. Walshe, I am able to mention that there is at present in Jervis-street Hospital a child, æt. 4, both of whose thighs and right humerus were fractured by being caught in the wheel of a car. All the broken bones were at once put up with the plaster apparatus. Immediately afterwards the little patient seemed quite at ease, and free from suffering, and has since continued to progress. The efficiency of the plaster in this case, and the difficulty which the application of two long splints would present, speak volumes.

The cases which I have noted (some twenty in number) may seem too few to give me such confidence in the apparatus, but I trust, for the reasons I mentioned, the society will excuse my bringing this mode of treatment forward, and that my explanation and advocacy may secure for it a more complete and satisfactory trial.

◆

CASE OF POISONING BY CARBOLIC ACID(a).

By R. W. Harley, L.R.C.P.

I wish to detail, very shortly, the history of a case of poisoning by carbolic acid, with the view of obtaining information on the subject, especially as to the best antidote for it.

On the 11th of last month, at a quarter past eight in the morning, I was sent for by my friend Dr. Brownrigg, of Sandford road, to render him what assistance I could in the following case:—About eight o'clock he had been called to Mr. Timothy Horan, of 16 Bushfield avenue, of whom he received the following account: He was about sixty-five years of age; he had been taking medicine for bronchitis, to which he was subject. Two-thirds of a bottle of the red impure carbolic acid had remained in his bed-room since some previous disinfecting had taken place. He had risen, as was his habit, about half-past seven. The morning was dark and foggy, and his family supposed he had drank carbolic acid in mistake for his medicine, as it was beside him on the table, with the measure-glass alongside it smelling strongly of the acid. The smell was all through the room, and strongly off his breath. He was sitting insensible in his chair, with his head hanging over the side of it; and, on being roused, only said, "Let me alone." About a quarter of an hour had then elapsed from the time of his taking the dose.

On Dr. Brownrigg's arrival, a few minutes after eight, he found him quite unconscious, with a strong smell of carbolic acid off his breath. His lips and tongue, and the mucous membrane of the throat and fauces, as far as he could see, were perfectly white; his heart was fluttering, and his pulse could not be counted. There had been no attempt at vomiting. Dr. Brownrigg endeavoured to pour some oil down his throat, but it flowed back. He then sent for me, as the nearest assistance he could think of, and in the meantime applied galvanism over the heart and chest, in hopes the patient might be roused sufficiently to swallow either an emetic or antidote. When I arrived the pulse was scarcely perceptible, and the heart was only audible under the stethoscope, and then very feebly so. A thick milky froth was coming from his lips and throat; his extremities were cold; his chest heaving, and his breathing laboured and stertorous; the eyes were fixed upwards, and the pupils contracted; he was in every sense moribund. We put sinapisms over the heart and stomach, hot jars to his feet and back, got his clothes off, and had him made as warm as possible. We tried to give him brandy and water, but even plain water came back, and the attempt to administer it brought on asphyxia. We were afraid to introduce the tube of the stomach-pump, the mucous membrane was so destroyed, and it seemed useless risking it. We administered a turpentine enema, which was retained, without producing any effect; and the heat was kept diligently applied to the surface of the body. He never rallied, but died about one o'clock the same day, about five and a half hours from the time he took it. The quantity he swallowed was about an ounce.

There was an inquest, but no autopsy. It seems probable that, had he recovered the shock, he would have died of the erosive effects of the poison.

◆

ALCOHOL AS A MEDICINE.

By James Edmunds, M.D.,

Late Senior Physician to the British Lying-in Hospital.

Mr. Skey is so manly and outspoken in all his habits that one is not surprised at his appearing a second time in the columns of the *Times*, to protest against a professional declaration which must have made him very uncomfortable. Mr. Skey, one of our most distinguished surgeons, and occupying a commanding position in the Profession, deliberately avows in the *Times* of the 8th ult., that he has taught his views on the use of alcohol "for a long succession of years, to some of the largest classes of Medical students assembled in London," and he invites a comparison of notes, in order that "the real value of alcohol in the treatment of disease may obtain its solution." This important question is one on which, in the columns of a Medical journal, some discussion may be of real service, and the more so, as Mr. Skey may be said to champion that very practice against which so many leading members of the Profession have thought it their duty to protest.

In Mr. Skey's letter to the *Times*, he takes the public into his confidence, and broadly announces that "all illnesses, in one stage or another, betoken debility," and that "for this condition of real weakness, he prescribes wine as a prominent remedy, to be administered at intervals, more or less according to the circumstances." In order "to exemplify this principle," he relates the following case:—

"About a year before Dr. Todd's death, I met him in consultation at the house of a young officer who was suffering from water in the chest, and from which by puncture I removed six pints of fluid. The operation concluded, the gentleman was a good deal, but not seriously, exhausted. His pulse had risen to 130 beats in the minute. Now, at this stage of the case I am relating, let any Medical man ask himself what measures he would have adopted to reduce the pulse towards the natural standard? Would he have done anything, or nothing, and thus taken the chance, a very indifferent one perhaps, of its falling spontaneously? Dr. Todd said to me, 'You and I shall not differ in the means of reducing that pulse,' and the patient was ordered one ounce of brandy with an equal quantity of water, every four hours. On the day following his pulse was reduced in number to 100, and on the following to 90, and his recovery was rapid."

(a) Read before the Surgical Society of Ireland. Discussion on the communication at page 140.

I do not know whether the case with which the readers of the *Times* are thus favoured is one of Mr. Skey's greatest successes with alcohol, but it appears to be a recital, *with variations*, of a case published by Mr. Skey, in 1867, in his lectures on "Hysteria," &c. In that work, however, the narrative closes with these words:—

"He took the only remedy that could have probably saved his life. He was ordered one ounce of brandy, diluted with an equal quantity of water, every *three* hours, and on the day following his pulse had fallen to 90, and he recovered. If this treatment were not sound it ought to have proved fatal." I venture to say that the discrepancies between these two statements are very remarkable. How came they into the picture of a typical case, drawn by the hand of a master for the purpose of "exemplifying the truth of a principle" which other leaders repudiate? In his book Mr. Skey states that the brandy was given every *three* hours, and that on the following day the pulse had fallen to 90. In the *Times* he states that the brandy was given every *four* hours, and that on the following day the pulse had fallen, not to 90 but to 100! As to the argument, it needs no formal analysis in a Medical journal. Every one knows that such a case will probably recover, and that an ounce of brandy every three or four hours, would be very unlikely to "prove fatal." Hundreds of practitioners could cite cases infinitely more conclusive, and in which treatment by simple rest, judicious feeding, and proper posture, without any alcoholics, has eventuated in speedy convalescence. Indeed, cases of hydrothorax in young persons, unless complicated with disease of the heart or kidneys, of which there is no mention in this case, almost always do well after puncture, and so soon as the heart and lungs are set free by the removal of the fluid the pulse falls as a matter of course. Yet this case is put before the readers of *The Times* as if the recovery depended upon the brandy that was given. In those very remarkable six lectures delivered to the students of Bartholomew's Hospital, and afterwards published through Longmans, more than five years ago, we find other utterances by Mr. Skey, which will perhaps illustrate more fully than his recent letters to the *Times*, the doctrine and practice against which the Profession has now protested. Mr. Skey introduces these lectures by laying down in sweeping terms the doctrine that all diseases are caused by debility, and that "wine is indispensable in the diet scale of the invalid, and for the tonic treatment of disease." He says "You cannot cure disease with a feeble pulse. Mend the pulse and Nature will do the rest of the work," and he concludes his introductory lecture by telling the students that in 1848, the quantity of wine he ordered for his patients at St. Bartholomew's Hospital, having been commented on by the Treasurer, he replied that he would do his best to raise the consumption of wine, from three pipes in the year to thirteen, and that in 1860, the quantity consumed reached that precise amount. Mr. Skey adds "and the same change of treatment prevails, more or less in every hospital in London." In short, Mr. Skey, who learnt his profession at a time when bleeding, starving, and mercurialising, were laid down as the cure for all diseases, now teaches that we should prescribe wine and brandy as universally as our fathers prescribed mercury and bleeding! And he cites cases which in his judgment (vide page 34), "go to exemplify this therapeutical principle, viz., 1. That stimulants alone can restore the vital powers under great and sudden prostration; and 2. That under great and sudden prostration the capacity of the system for stimulants is enormous, and that they may be administered to almost any amount with safety." I quote from this work the following "cases" as a fair sample of the way in which Mr. Skey exemplifies what he calls "this therapeutical principle."

CASE 1. (page 11.) "One of the worst cases of milk abscess that I ever saw, was that of a young woman in St. Bartholomew's Hospital whose husband struggled to support a family of seven persons on about as many shillings a week. This woman was confined with twins, which she nourished on a daily allowance of half a pint of bad beer, and for which misery the funds of St. Bartholomew's Hospital did ample penance. The cause is debility,—the effect, abscess. There are two agents in addition to good nourishment, especially applicable to the treatment of a case of this kind,—bark and wine."

CASE 2. (page 15.) "A gentleman with a weak pulse is told by his physician to take wine freely, and he indulges in a bottle of claret at and after dinner, and by so doing he considers himself to have obeyed the injunction of his Medical adviser. Now, I shall select port wine as the standard by which I regulate the advice I give under the above circumstances, and I am of opinion that for the purposes of health, three or four glasses of wine is the maximum quantity that, taken at any one time, can be serviceable."

CASE 3. (page 22.) "In the case of the late Lord R——, æt. 54, whose recent and sudden death caused so painful a sensation, the daily consumption of two or even three bottles of wine left his pulse as it found it, at 50 or 52. In the two months during which he was under my care, I prescribed stimulants to the full extent of prudence, but he was as calm and as free from all indications of excess in the evening, as in the morning. His confinement to his couch was limited to the additional term of ten days, when I assured him he should take a drive. He struck his thigh a smart blow with his open hand to prove to me how free his limb was from pain. This occurred late in the afternoon. At half-past ten, he had some difficulty of breathing, and he broke out into a profuse perspiration. Stimulants availed him not, and at half-past eleven he was dead."

CASE 4. (page 30.) "A young lady whose daily consumption of wine has never exceeded two glasses, oppressed by the heat of a crowded room, faints. The heart and the brain have failed in their functions by reason of the imperfect oxygenisation of the blood. Recovering from the first stage of sudden depression of her vital powers, her symptoms pass into those of hysteria. We have all witnessed cases of the kind. Ordinary and mild stimulants are unavailing and make no impression. An hour, two hours have elapsed, and she is yet prostrate. Before her recovery the girl has consumed three wine glass-fuls, or upwards of half-a-pint of brandy and other cordials, and often more."

It will be seen from these "cases" that the gist of the "doctrine and treatment," which Mr. Skey has thus taught for so many years to the present generation of Medical men is "give wine and brandy as a remedy for starvation in a poor nursing mother," when she ought to have been advised to spend her little money in oatmeal and milk. "Give alcohol to mend the pulse, and as a cure for feeble heart," although the case of Lord R——, as narrated by Mr. Skey himself, proves that "two or three bottles of wine a day left the pulse precisely as it found it," and it is well known that wine will no more cure a weak heart in a man, than it will cure broken knees in a horse. "Give half-a-pint of brandy and other cordials, and often more, to a young lady who faints from the heat and impure air of a crowded room," when if simply treated with fresh air, loosened clothing, and cold water, she would rally at once, instead of remaining in a state of collapse for "an hour or two."

It is against such "doctrine and treatment," that the recent medical declaration is directed, and probably it is the weightiest service of this kind which the Profession has recently rendered to the public. For years I have been in the habit of prescribing alcohol with "as much care as any other powerful drug," and having watched its effects most carefully, I have arrived at the conclusion that alcohol is not indispensable, either for "the diet scale of the invalid," or for "the tonic treatment of disease." I believe that alcohol is one of the most powerful drugs in the materia medica, and, when used with an accurate perception of its physiological influence, most useful. But I think it will be found that the true nature of the effects of alcohol are exemplified in the narcosis of full intoxication, when nervous and muscular power are alike in abeyance. In smaller doses I believe alcohol to be precisely the same in the nature of its effects, *i.e.*. that it is always a narcotic. Upon what grounds it is held that by lessening the amount of the dose, the nature of the effect is reversed, and alcohol becomes in small doses a stimulant, I have never been able to discover. If Mr. Skey, or some other reader of this journal would clearly and categorically state the grounds for such a doctrine, we should be on the right road to solve a great question.

Nothing could be more disheartening to anxious practitioners than the utterly loose way in which alcohol is recommended in the treatment of disease. Those who boldly prescribe it in a purely empirical way, though beyond the reach of direct refutation, are easily met by the empirical appeal to statistics. But there are distinguished men, such as Mr. Skey, who talk about their "doctrine," and prescribe alcohol, now as *a stimulant*, now as *a food*, now as *a medicine*, without ever defining the ideas which they intend those terms to express. I venture to offer some definitions, in order to promote the exact discussion of these points. What is a food? A food is a substance which being soluble in the blood and innocent, can be decomposed in the body, and made to give up forces which replenish the vital energies. What is a stimulant? A stimulant is an agent which exhausts vital power without replenishing it. To an exhausted horse, a measure of corn, with the time and water necessary for digesting it, is a real replenishment of his energies, and he goes on through another stage of his journey without injury. The corn is *a food*, and has furnished the forces which have been expended. If on the other hand the spur has been applied; the next stage may be equally accomplished, but at the expense of the constitution of the horse, the spur having obviously got strength out of the animal without putting any in. The spur is *a stimulant.* When we prescribe alcohol as *a drug* in order to induce some physiological modification of the system, we have a highly complex problem to deal with, and one which cannot be dismissed in a paragraph or a sentence. But there is one thing of which we are certain, and it is this: that the alcohol is a powerful narcotic agent, the most obvious properties of which are to lessen oxydation and consequently diminish alike the evolution of vital force and the elimination of effete matters. In addition to the narcotic influence, there follows a perturbation which is often taken by superficial observers as evidence of *stimulation*, but which is chiefly the result of conservative efforts on the part of the system to eliminate the poison. The edge is taken off the mind, the harmony and delicacy of the muscular actions are impaired, and the lower faculties run riot as the balance and governance of the system give way to advancing narcotism; the man sees two candles where there are only one, he becomes strong enough to fight all the world, and at length he can walk so well that the pavement rises up and strikes him on the head. Step by step, as the alcohol is exhaled from the system, this "stimulated" condition passes off, and the fetid breath, the filthy exhalations from the skin, the poisoned state of body, are all such as might have been predicted *a priori* from the mere chemical influence which a little alcohol vapour manifests upon the flame of a burning candle. On the other hand, a large and sudden dose of alcohol kills a man as surely and as speedily as a teaspoonful of prussic acid. Such are the obvious results of that agent, which Mr. Skey now advocates as essential for all conditions of real weakness!

Mr. Skey suggests a comparison of notes of cases. Nothing can be more delusive than isolated cases, and especially if the facts are recorded without exactness, or the cases are such that the conditions necessary for applying the numerical method are absent. But without multiplying such useless materials, I can submit some statistics drawn from the records of a public Institution, and which are still open to investigation by others. I therefore give the following table of the data recorded in connection with the indoor patients of the British Lying-in Hospital. It shows the mortality of mother and newly-born children, firstly—for a term of five years while alcoholics were prescribed very freely, and secondly, for a term of one year while alcoholics were used with extreme infrequency:—

STATISTICS OF THE BRITISH LYING-IN HOSPITAL, FOR THE SIX YEARS ENDING FEBRUARY 28TH, 1869.

Date.	Total Deliveries.	Maternal Deaths.	Children's Deaths. Totals.	Children's Deaths. Born Dead.	Children's Deaths. Born Alive.
1863. March 1 to Dec. 31 (10 months) .	120	1	7	3	4
1864. Jan. 1 to Dec. 31 (12 months) .	200	0	15	10	5
1865. Jan. 1 to Dec. 31 " .	232	5	21	10	11
1866. Jan. 1 to Dec. 31 " .	192	4	29	8	21
1867. Jan. 1 to Dec. 31 " .	290	7	24	13	11
1868. Jan. 1 to Feb. 29 (2 months) .	12	1	2	2	0
Totals for the first five years— .	1,046	18	98	46	52
Average Ratios for ditto . .	—	1 in 58	1 in 10 2-3rds.	1 in 23	1 in 20
March 1, 1868, to Feb. 28, 1869 (12 months)	167	1	8	6	2

It will be observed that the mortality in the Hospital during the first five years was three times as great among the mothers', and four times as great among the live-born children as that which occurred during the subsequent twelvemonths. In reference to the latter period, the sole maternal death which occurred took place in a poor woman who entered the hospital in an advanced state of consumption, and, having passed safely through her delivery, died on the eleventh day afterwards. Of the two deaths which occurred among the live-born children, one was due to congenital absence of the brain, the child dying on the third day, and the skull being found entirely occupied with serous fluid excepting a few vascular shreds and nervous ganglia, which lay at the bottom of the cranial cavity. The 167 patients of the latter period were in Hospital a total of 2,974 days—or an average term of *eighteen* days each; while the 259 patients of the previous twelve months were found to have been in hospital a total of 4,147 days—or an average term of *sixteen* days each. It only remains to add that during the last twelve months no selection of patients was made, and that not a single patient who offered was refused admission on the ground of general ill health, nor indeed, so far as I know, on any other ground.

There was, however, one important fact. During the first half of the last twelve months the patients had only one half-pint of beer daily as had long been customary in the diet of the Hospital, and scarcely any alcoholics were prescribed medically. During the last six months this solitary half-pint of beer was cut off, and replaced by an extra half-pint of milk. During the previous years port wine, brandy, &c., had been prescribed with considerable freedom, and that practice was afterwards returned to, by the able physicians who succeeded me in the medical charge of the in-patients. Tthe mortality of the Hospital has since been higher than ever. I recommend these records to further study on the part of our Hospital Medical Officers. I believe that they will be found to justify an entire reversal of the doctrine and practice with regard to alcohol, which has become prevalent of late years.

◆

Transactions of Societies.

SURGICAL SOCIETY OF IRELAND.

January 19, 1872.

J. H. Wharton, F.R.C.S., President of the Royal College of Surgeons, in the chair.

The Society met at half-past eight o'clock p.m.

Mr. Richardson read the minutes of the last meeting.

REMOVAL OF THE OS CALCIS.

Mr. W. T. Stoker exhibited for Mr. Croly an "Os Calcis," which he had removed from the left foot of a patient in the City of Dublin Hospital. The only interest attaching to it was the comparative rarity of the removal of the whole bone. Only a few similar operations had been performed in England. He could not describe the incisions made in this case, but he believed they were a modification of those recommended by Mr. Erichsen.

Mr. Stoker also exhibited a

GLOVE OF CUTICLE

from the hand of a young man whom Mr. Croly had attended in private. He was a farmer's son, 25 years of age. He was attacked with confluent small-pox before Christmas, and on the 13th day he got scarlatina. The glove came away subsequently. Such specimens were not uncommon, but this one was curious because it represented very well the marks of the small-pox. Dr. Barker had preserved it very beautifully in turpentine.

In reply to the President,

Mr. Stoker said that the patient, from whom the "Os Calcis" was removed, got a blow on the heel, which subsequently inflamed. When he came to the hospital he had a sinus on the side of the outer malleolus. A portion of bone was gouged out, but as that did not give relief the whole of the calcis was removed.

Mr. Robert W. Harley read a

CASE OF POISONING BY CARBOLIC ACID.

An abstract of which will be found at page 137.

Mr. R. W. Harley added: The case, so far as I can learn, is rather unusual. I have asked a great many gentlemen, but I have not met one who has treated such a case. We (Dr. Brownrigg and myself) are anxious to hear what is the best antidote, and whether we left anything undone.

Mr. Richardson: Was the urine coloured?

Mr. Harley: He had not passed any.

Mr. H. Kennedy said there were some cases of this kind reported. One occurred last year in a workhouse in England, where serious effects followed its application outwardly. He had read of one case where death, and of another where very bad effects followed its internal use. He did not think anything could be done in such cases, except to give stimulants, and probably the spirits of turpentine was given with that object. Two or three ounces of brandy might have done better.

Dr. Mapother thought the case was the first which had been reported in this country, but in 1866 he received from Brownlow hill Workhouse, Liverpool, the particulars of a case where death occurred in two and a half hours. It was during the cholera epidemic, when the oil was used as a disinfectant, and he thought about four ounces were swallowed by one of the nurses. There was no doubt that death would occur by leading to coagulation of the albuminous lining of the œsophagus, and it was hard to say what remedy could be administered. In the case to which he referred they made the patient swallow oil. The coagulating powers of this poison were so strong that he had found it to be a more perfect test for albumen than any they had. The only suggestive, in a preventive way, would be that all quantities of carbolic acid should be sent out in the same kind of bottles as liniments, covered with sand paper. It was a most valuable disinfectant, as he had an opportunity of knowing, but a very dangerous one.

The **President**: Do you know the solubility of carbolic acid in oil?

Dr. Mapother: One to six is the Lister preparation. I have always used the pure oil dissolved in alcohol as a precipitant for albumen in urine. The ordinary carbolic acid at 4s. per gallon is impure. It is mixed with naphtha and various other impure compounds.

The **President** asked Mr. Harley if there was any vomiting.

Mr. Harley said there was not.

Mr. Stapleton asked Dr. Mapother whether he considered carbolic or chromic acid the better disinfectant.

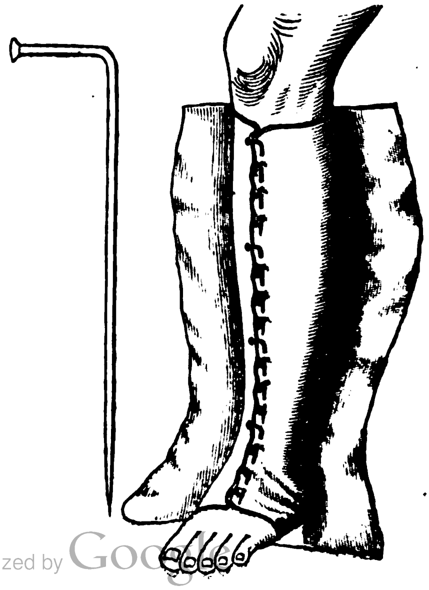
Dr. Mapother: I have not much information on the subject of chromic acid, but from its being volatile I should think it very much inferior.

Mr. Harley, in reply, submitted an extract from a letter received from the manufacturers of the carbolic oil in the present case. All the books he had consulted were devoid of any information as to antidotes for this poison, or as to its chemical history. He believed it was first of all a sort of impure creasote, used for steeping railway sleepers, and that the pine wood gave it the red colour. Whether that made it more deleterious or not he did not know. He was glad to hear from Dr. Kennedy that they had done all they could have done under the circumstances, and from Dr. Mapother that he had nothing to suggest but oil. They had decided to give oil, but there was a milky froth coming in such quantities from his throat that even cold water was rejected, and they then thought it would be better to leave him alone, than to run the risk of choking him.

Mr. A. H. Corley read a paper

ON THE BAVARIAN PLASTER APPARATUS FOR FRACTURES,

which will be found at page 136.



Mr. Corley explained the application of the apparatus.

The **President** said he had listened to the paper with great pleasure, and he was sure they all felt greatly obliged to Mr. Corley for bringing forward this mode of treating fractures. He had seen his colleague, Mr. White, use it. That morning he (the President) had had an opportunity of seeing such a case as Mr. Corley had exhibited the apparatus for. Nothing could be more expeditiously or efficiently done. It only took about five minutes to put up a fracture of the tibia. Mr. White had a stiff case for the patient's leg almost immediately, to the man's great comfort and relief. He had also seen Mr. White use a modified many-tailed bandage, which he called by Mr. Stapleton's name. All present who knew the great difficulty of getting a good bandage would appreciate it.

Mr. Stapleton said he had seen several cases treated with this apparatus by Mr. Corley, and he must certainly say that in Pott's fracture he considered it one of the greatest blessings to the patient, and one of the greatest improvements in surgery. He himself had for a long time discarded Dupuytren's splint. At the time it was brought before the Society he combatted the great advantages that were claimed for it. He (Mr. Stapleton) used a box splint, with pads. If they put on Dupuytren's splint in the original way it would not do. It had been nicked and notched by surgeons to try to retain it in its place, but notwithstanding it still slipped. But he had never seen such advantage as was given by this apparatus in Pott's dislocation. As to the many-tailed bandage he (Mr. Stapleton) was first led to use it in fractures of the thigh. In fractures of that bone, put up in Liston's long splint, with the bandage round the foot and up the thigh, if you wanted to see what was going on you had to unroll the whole bandage. Any one who had had a number of fractured thighs under his care at one time would know how laborious this was. He had had eleven fractured thighs under his care at one time, and he then took this plan of using the old many-tailed bandage. If one part was loose it could be tightened, or all could be loosened to look at the fracture. In treating fracture of the thigh he used three splints. He never disturbed the leg, but simply undid the bandage, and saw what was going on. It might be said, "Oh, put on a starch bandage," but he had seen some very ugly accidents from leaving starch bandages on too long. Sometimes when a surgeon thought that he was going to have a nice limb, and left it in the bandage for six weeks, he found a little more angular deformity than he wished.

Dr. Mapother said since Mr. Corley mentioned the use of this apparatus to him he had tried it in club-foot, and in two cases it had been fairly successful. In another, on account of the extremely small size of the foot, it was not easily applied, but in two cases where the children were three or four years' old it suited admirably. After division of the tendo Achillis, he placed the foot in proper position, and then with this admirable apparatus he had complete extension, and the result was satisfactory. In another case he applied a roller covered with plaster-of-Paris, and covered with an ordinary bandage. Mr. Corley had called this the Bavarian apparatus. He was sure he had forgotten to state, as he did when he first mentioned the subject, that it was introduced to this kingdom by Asst.-Surgeon Moffett, a pupil of the College in 1855, and a licentiate. He had noticed it in use during the Franco-Prussian war, and had described it in his book on "Ambulance Work."

Mr. Stapleton observed that this was not what was called the plaster bandage. What was used in Berlin, where he had seen it used, was a thin material, which was dusted very thickly with plaster-of-Paris. It was then soaked in water, and rolled round the limb. The material used was very open, like what they in this country called a lint bandage.

Mr. Fleming said the apparatus which had been just described by Mr. Stapleton was the one which had been used here for a long time. He used it himself in the Richmond hospital, and if he was not mistaken, it was a German who introduced it to this country. He believed he was a Professor in one of the principal schools, but he forgot his name. It consisted of a gauzy bandage of very open work, and was dusted over, he believed, with a preparation of plaster. It was then damped and applied to the limb, and plaster was rapidly applied with the hand to the outside. It quickly formed a tolerably solid case, but it took a long time to dry satisfactorily. Some of his cases turned out well, but in some of them there was considerable deformity. He thought they were much indebted to Mr. Corley for bringing this new apparatus before the Society. In the first place it was capable of extremely easy and rapid application; in the next it was of great advantage to the surgeon, because it enabled him to watch carefully the progress of the case; and if, as it did happen in injuries such as those of the ankle-joint there was effusion in twenty-four hours or so after, it was of great advantage that they should have the opportunity of ascertaining whether such a condition existed, and of applying the necessary remedies. He thought hospital surgeons should be very glad to have the opportunity of putting this apparatus into use as often as they had the opportunity.

Mr. Richardson observed that many years ago M. Seutin, owing to the accidents liable to occur under the use of the immovable starch apparatus, such as excoriations and gangrene, substituted for it the starched apparatus having the properties of movability and immovability, and which he named the *Amovo-Inamovible* apparatus, the principle being identical with that just illustrated by Mr. Corley. In M. Seutin's starch apparatus the movability is imparted to it by dividing the apparatus, when dry, its whole length in front, and after some time should the limb shrink, he removes some of the edges of the apparatus to enable it to fit close to the limb and give it firm support. This apparatus has been compared by Goffres in his "*Précis Iconographique de Bandages, Pansements et Appareils,*" to a bi-valve shell. Indeed, in Goffre's book the bi-valve term is also applied to the plaster apparatus constructed on this principle.

Mr. Stapleton said that an apparatus had to be used to cut it.

Mr. Richardson said that was another matter. Seutin had established the bi-valve principle, and this name is applied to the *Amovo-Inamovible* starch, and even to the plaster apparatus in Goffre's work. He (Mr. Richardson) had often made Seutin's *Amovo-Inamovible* apparatus, and found that after it had been removed and re-applied two or three times, the starch cracked along the middle line posteriorly, and allowed of its easy removal and re-application.

The **President** wished to know how Mr. Corley put up Colles's fracture in this apparatus, because one of its advantages was its universal applicability.

Mr. Corley, in reply, said that with reference to Dr. Mapother's observation, he had stated in his previous communication that he did not claim the slightest originality in the matter. He got a description of the apparatus in one of the Army Medical Reports. It struck him that it would be a most convenient apparatus, and having tried it he found that it exceeded his most sanguine expectations. The history given by Mr. Moffett, who was a resident pupil at Jervis-street Hospital at the same time as Mr. Walsh, was in a communication made by him while at Netley, and he mentioned that it was communicated to him by Dr. Streidlinger, as the apparatus used in the Bavarian ambulances, but it was intended rather as a temporary than, as he understood Mr. Moffet's paper, a permanent arrangement. He (Mr. Corley) found on trial that there were few fractures to which it was not applicable. As to Mr. Richardson's observations about the bi-valve, he had only to say that in this case the line of stitching prevented the plaster on each side from meeting, so that a hinge was left like the back of a book.

Mr. Richardson observed that the term bi-valve had been long ago applied in French books to this apparatus.

Mr. Corley continued to say that the starch bandage took two or three days to harden. He remembered, as a student, attending an hospital where the "succession duty" plan was carried on by the surgeons, and he saw a fracture put up on one of the last couple of days of the month. It was not held in position, and the in-coming surgeon did not take the same interest in the case, and he remembered that the limb presented a very remarkable elbow on the external side. It impressed him very much with the importance of keeping fractures in position while the starch was hardening. That would take three days, while the apparatus, if the plaster was good, would be hard in three or four minutes. With regard to Colles's fracture, he held it securely in his hand in the ordinary way, and put a pad over the dorsal prominence, just where the splint recommended by Dr. Smith pressed. While so holding the fracture he grasped the outer layers, so as to press, and to secure the same object at the lower end, that was secured by the keel in Gordon's splint. The fracture in which he tried it was doing well. It had been put up in Gordon's splint. The other was put up in the ordinary pistol splint, and was giving the patient great pain and uneasiness. He put the fracture up in this apparatus, and the man was able to get up next day, and never had the least pain afterwards.

MR. E. HAMILTON read a paper on "Excision of the Knee-Joint," which will be given in our next.

SHEFFIELD LITERARY AND PHILOSOPHICAL INSTITUTION.

THE 50th anniversary of the Sheffield Literary and Philosophical Institution was celebrated on the 2nd inst., when the learned President, Mr. H. C. Sorby, F.R.S., delivered the address.

The President said: On behalf of the Literary and Philosophical Society, I have much pleasure, on the fiftieth year of its existence as an institution, in welcoming you all at this conversazione, and trust that you will find the arrangements satisfactory. I will not weary you by describing the various objects exhibited, since the catalogue will show what they are, and an actual inspection will be far better than any brief description. There are, however, a few to which I would call attention. One of the leading features in this conversazione will be the exhibition on a large scale with the lime light of photographs illustrating the great events which have lately occurred in Paris. I have no doubt that, as mere pictures, they will give you much pleasure, but I am more anxious that you should look upon them as a lesson in history, having a greater practical bearing on ourselves than any that can be learned from the classic history of Greece or Rome. You will also, I hope, be pleased to examine other useful applications of photography and a number of ingenious mechanical contrivances. Amongst these a calculating machine, intended for general use where much computation is required; and, whilst alluding to this, I will take the opportunity to congratulate this society and the town at large on our having amongst us a gentleman who has invented—I cannot say a machine, but at all events mental machinery—by means of which certain most difficult mathematical problems may be solved, which had resisted all methods previously known. I need scarcely say that I allude to our friend Mr. Earnshaw and to his recent work on a new method of integrating partial differential equations. You will, I am sure, accord your best thanks to all who have lent objects for exhibition. On previous occasions the Geographical Society of London has assisted us in this manner; and it is now in our power to do something in return. As you are aware that society is about to send out an expedition to search for Livingstone; and, on account of the illiberal conduct of the Government, it is necessary to appeal to private liberality. I shall be most happy to receive and transmit to the society anything that may be contributed in this town towards such a laudable undertaking. I may here say that in the other room you will be able to examine a book of spirited sketches, taken in South Africa, by Mr. Baines, the well-known African traveller. Whatever may be said of the scholastic discussions of a by-gone age, it would be a great error to suppose that modern science is a mere system of speculation, to be adopted or rejected at pleasure, and which some might conscientiously regard as having injurious tendencies. Science is simply accurate knowledge—accurate deductions from accurate facts. I contend that nothing false is science, and that to imagine that, in the long run, any mischief can result from knowing the truth, is to be classed only with such sentiments as that it is folly to be wise. Placed as we are, as material beings amongst material objects, our power and happiness mainly depend on our knowledge of the laws which regulate the operation of those objects on each other, and on ourselves physically and physiologically. If we foolishly oppose these laws we suffer or perish, whereas, if we direct them with intelligence, we may work wonders. As an illustration, I will refer to the model of the Moncrieff gun-carriage, exhibited this evening. Hitherto the recoil was an objection, or at all events useless, but by a simple application of mechanical principles, the force can now be utilised, and made instrumental in protecting the men and the gun, and employed to raise it in a position for the next shot. There can be no doubt that our knowledge of the commonest objects that surround us is only in its infancy, and yet so much is known, that, if it were conscientiously practised, the happiness of mankind would be enormously increased. But alas! how ignorant many are of the simplest principles involved in the operations of Nature. I feel persuaded that we need not go far to find hundreds who would not be surprised if the moon were to rise in the west, and who could not give any intelligent reason why animals are obliged to eat and drink. This ignorance, even amongst the somewhat educated classes, can only be removed by the full recognition of the claims of natural science to form a prominent part of general education. If we could but extend such knowledge, and if men would but see the folly of knowing what to do and not practising it what a change for the better would result! I am quite willing to admit that science is advanced chiefly by the labours of individual explorers, but, at the same time, societies like our own may do much to spread its influence. It is on this ground that I claim your further support for this institution. The number present here this evening is a proof that our annual conversazione is popular. No one could be more pleased than I am that it is so, but I should be far more pleased if I could flatter myself with the belief that all had come to pay homage to science. At all events I will conclude by expressing a hope that, after having spent a pleasant evening under the auspices of literature and philosophy, each in his own particular sphere will do what he can to promote their interests, and to extend this beneficial influence of an accurate knowledge and an intelligent application of the laws of Nature.

◆

QUACK DOCTORS AND THE AMERICAN NEWSPAPERS.

JUDGE PIERCE, of Philadelphia, in a recent charge to the Grand Jury, made the following remarks:—

"By the Act of 16th of March, 1870, it shall not be lawful to print or publish advertisements, of medicines, drugs, nostrums, or apparatus for the cure of secret or venereal diseases, or for the cure of those diseases peculiarly appertaining to females; . . . and every such person so offending shall be guilty of a misdemeanor, and shall, upon conviction thereof, be fined in any sum not exceeding 1,000 dols. or undergo an imprisonment not exceeding six months, or both or either, at the discretion of the Court. A second section of the Act prohibits the advertisement and sale of any secret nostrum or drug, purporting to be for the use of females, for the purpose of preventing conception, or of procuring abortion or miscarriage, under the penalty of being deemed guilty of a misdemeanor, and upon conviction thereof to be fined in any sum not exceeding 1,000 dols. or be imprisoned in the county jail not exceeding six months, or both at the discretion of the Court.

"One of these manufacturers of nostrums, seems to have taken the columns of some of these newspapers into his keeping, and daily thrusts into the faces of hundreds of thousands of this community, advertisements, more or less thinly veiled, which are intended to call attention to his medicines for the cure of secret diseases.

"I recommend this matter to your attention. These indecent advertisements are prohibited by law; are offensive to good taste; are subversive of good morals, and tend to public corruption.

"I hope, without further attention being called to the matter, that these papers will cease publishing these prohibited advertisements; but, if they should not, it may be your duty and the duty of the officers of the law to take more direct action in the matter."

Apothecaries' Hall of England.—At a Court of Examiners held on the 8th inst., the following gentlemen, having passed the necessary examination, received the L.S.A. Diploma viz:—Messrs. S. L. Dobie, of Irthington, Carlisle; F. E. Jackson, of Chertsey, Surrey; and P. B. Stoney, of St. Bartholomew's Hospital. And the following passed the primary professional examination, viz.:—Messrs. C. B. Dalton, of Guy's Hospital; A. S. Morton, of the London Hospital; and W. N. Walker, of University College.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, FEBRUARY 14, 1872.

THE SESSION.

ALTHOUGH there will be apparently no lack of Parliamentary talk on subjects that interest our Profession, some of the greatest objects of Medical aspiration found no place in the Queen's Speech, and will probably obtain no hearing. Thus, what has been called Medical reform is to be still postponed, to give perhaps the General Medical Council and the too numerous licensing bodies further opportunities of vexing all practical men with interminable talk and obstructive procrastination.

This is perhaps partly due to ourselves. The other day the editor of a daily paper told us confidentially that, in his opinion, we deserved no more than we got, because we did not hang together. The Medical Profession, he declared, has no cohesion. What one man says others are sure to deny; and even when a really good scheme is projected, and nothing can be said against it, the masses will not take it up, but let the author bear all the burden and heat of the day. If he should succeed, they would take the benefit in a thankless spirit; and if he fail, they will never appreciate his earnestness, or be grateful for his sacrifice.

Of course, we could not admit this, and put in excuse all that may be said about our absorbing occupations. Nevertheless, we deem it well to mention the circumstance, that our readers may see from that conversation the drift of public opinion about the Profession, and from it learn that apathy can never achieve anything. There are too many who have kept so aloof from questions of public interest, that the united voice of the Profession is never heard, and the public seems likely to conclude that only technical matters are cared for by us. This should not be. The interest of the Profession is the interest of the public; and, until that truth is perceived, we shall never exercise that influence on public matters which naturally belongs to our Profession.

There is, however, to be a Sanitary Bill, and one too of large pretensions, founded on the report of the Sanitary Commission. We have before referred to its labours, and to many points that must be debated in connection with this measure. The Bill is to be mainly one of consolidation—not to say codification; and it is not improbable that its progress will bring into full relief the need of more Medical members of Parliament. We are not foolish enough to wish to regulate through mere Professional men the sanitary legislation of the country. We know that the rights of property and the liberty of the subject must be considered as well as the public health; but we do make bold to assert that the wisdom of Parliament itself must be foolishness on Medical and sanitary matters unless it contain members of the Profession.

On this plea alone we might fairly rest the claim of medicine to be represented in the House of Lords—side by side with the sister professions. Did the Upper House only contain an adequate representation of the Profession, it would be a most suitable assembly in which to initiate and mature great measures of Public Health. And what a relief it would be to the over-worked House of Commons to have such work accomplished at the early part of the Session by a competent body, and brought down to it for approval in a condition fit for rapid enactment. But no, it is not to be. That is, not yet, though clearly the time is coming when some minister will be bold enough to bring about a reform for which we believe public opinion is nearly ripe.

Nothing would go farther to strengthen the position of the Peers than the introduction into their ranks of representatives of medicine and science; and we have reason to know that this opinion is entertained by some of the Peers themselves.

At the present time the Government—ignorant as it must be of sanitary matters—has no one to whom it can naturally look. Now and then it applies to the College of Physicians. This is not a speedy nor a natural plan. Sometimes the Privy Council endorses the views of its medical officer—who may be crotchety, and, in any case, has virtually no responsibility. Sometimes again, a Cabinet Minister asks a question from any Medical man he may be acquainted with—or, worse still, refers an important medical inquiry to a physician selected at hap-hazard, as poor Mr. Bruce lately asked Sir W. Gull's opinion in reference to the sanity of a criminal, about whom the newspapers badgered him. Could anything be more absurd than to see a physician, because he had been called to see a Prince, set to revise the verdict of a jury. But no doubt Mr. Bruce thought it would be popular; and with no representation of the Profession in high places, he only fell into the evil precedent of his predecessors. The moral is, however, plain enough. The Profession must rouse itself, and assert its place. For this reason we hope to hear no more disparagement of political Medical men by their brethren.

Happily, in the House of Commons there is a small band of Medical men, and we hope that every election may increase it. If the Profession would exert itself this would be easy, and then great and beneficial reforms would be effected.

Sir D. Corrigan and Sir John Gray both have the interest of the Profession at heart. Ireland does well to send them. Dr. Brewer is one of the most indefatigable members of the House, and has also done much for us on the Asylums Board and elsewhere. He is justly appreciated at Colchester. Indeed, were it not for that, his party would probably lose that borough. He therefore deserves the peculiar thanks of the Government, who could not fail to attend to him. We should be glad to see him assume the position of leader of the Medical members, and bring in a Medical Bill of his own.

There are others anxious to serve us, and unless some great change takes place soon, we trust all will unite to assert for medicine its proper place in the State.

◆

THE SUPPLY OF VACCINE LYMPH FOR IRELAND.

The small-pox epidemic and the consequent demand for vaccine virus for the purpose of re-vaccination, have very naturally resuscitated a discussion which, some years ago, was pursued with much acrimony as to the existing arrangements for the supply of lymph. That the present system is utterly inadequate for the demands of a serious epidemic, recent experiences have proved. But it needs no argument to show that an arrangement which, while it gives to England the utmost facility for vaccination, puts upon Ireland a more or less prohibitory tax for the necessary vaccination material is utterly unjustifiable. In England, as most of our readers know, pure lymph preserved in the best manner is supplied gratuitously, without even the expense of a postage stamp, to any registered Medical practitioner. We quote from the circular of the National Vaccine Establishment.

The preserved lymph of the National Vaccine Establishment is sent out as follows :—(1) liquid, in hermetically sealed capillary tubes ; (2) dry, on ivory points ; (3) dry, between plates of glass.

Lymph may be obtained, by personal application, from Mr. Tomkins, Inspector of the Establishment, at the Central Station, between the hours of 10 a.m. and 2 p.m. Letters of application for lymph may be addressed, not stamped.

To meet the expenses of this gratuitous distribution—a system of which we admit the national prudence and propriety—a grant was made from the Consolidated Fund last year of the following sums :—

Five Vaccinators	**£472**
Incidental Expenses . . .	**928**
Grants to Public Vaccinators . .	**8,000**
Total	£9,400

Thus it appears that, in England the state sets aside nearly £10,000 a year for vaccination, and is thus enabled to supply abundance of lymph without cost to every qualified person. Let us see how Ireland stands. The Dublin Cow-pock Institution receives a grant of £400 a year, in consideration of which it maintains five auxiliaries in Dublin, and up to ten days ago charged half-a-crown for a few lymph points to all private practitioners, and a guinea a year for a constant supply to each union which subscribes.

We frankly appeal to the common sense of our readers, whether such a grant or such a system is just or equitable, and whether it is prudent that Ireland should be left under the pressure of a serious epidemic to so miserable a provision.

In the year 1860, Dr. Long, of Dublin, called attention to the subject in a pamphlet, but to this day nothing has been done. We make no charge against the administration of the Dublin Cow-pock Institution, nor are we in a position to criticise the expenditure of the grant of £400, simply because the directors have persistently refused and still refuse to give any account whatever accessible to us of its disbursement. Of itself, this is a fact calculated to excite suspicions and to give strength to adverse opinions, and it shows that the managing body of this public department is not in the vein for too much impertinent scrutiny. Without, however, assuming too much, we do not hesitate to say that it is a crying grievance that the protection from small-pox should be in Ireland doled out at a high rate, at the same moment that in England the state willingly provides for an abundant gratuitous supply. As to its other functions, we venture to think that the branches of the Dublin Cow-pock Institution have, in the presence of the Dispensary Vaccination arrangement, no important *rôle* to play, and as a preliminary to a complete readjustment of the grant and the organisation, we suggest that the miserable £400 a year might be much better applied to their maintenance.

Within the last fortnight, the Institution has reduced its price to 6d. in view of the present emergency ; but even if we could hope that this charge would be permanent, we would still hold the present Irish system to be self-condemned.

◆

SCOTLAND.

EDINBURGH.

The Lady Students.—In answer to a petition from Miss Jex Blake, the University Court has agreed, in accordance with the terms of a resolution passed at a former meeting, to receive the names of extra-academical teachers, and consider their respective fitness to hold Medical classes for women, who have in this or former sessions been matriculated students of the University, and the conditions and regulations under which such classes shall be held. Miss Blake's petition requested that arrangements should be made for completing the medical education of herself and the other ladies, irrespective of graduation.

The installation of Sir W. Stirling Maxwell, Bart., as Lord Rector of the University took place on the 6th. Very little of the excellent address delivered by Sir William was audible, on account of the disgraceful conduct of the students, who kept up an incessant noise, notwithstanding frequent remonstrances on the part of the Principal and several of the professors.

Lord Mackenzie has issued an interlocutor continuing the interdict against the Infirmary managers appointed at the meeting of contributors on 1st January. This decision prevents firms voting at the meeting of contributors. No appeal will be taken against this decision, but the case will shortly appear before Lord Gifford on the merits.

◆

Notes on Current Topics.

Increase of Temperature in Death.

M. Peter has published a communication in the *Gazette Hebdomadaire* of the 26th of January, in which he proves the following propositions :—1. That the temperature of the body increases at the moment of dissolution arising from acute disease. 2. That death takes place in these cases from asphyxia. 3. That the greater the depreciation of energy in the organism the greater is the increase of temperature.

A Medico-Ethical Difficulty.

The *Philadelphia Medical Reporter* narrates the circumstances of a medico-ethical difficulty which has given rise to much excitement in Medical circles in America. The Massachusetts State Medical Society one day rejected a friend of Dr. Storer; Dr. Storer was indignant and swore vengeance in unmistakeable terms.

At the meeting of the American Medical Association, he secured the rejection of the Massachusetts State Medical Society, on the ground that that Society admitted homœopathic practitioners! This point was proved, and the venerable society was placed on the black list, to the unutterable disgust of its members.

It appears that the Society, by its charter from the State, is obliged to admit every physician of good moral standing, and who can undergo an examination by a board appointed for the purpose. The "system" which they profess, cannot be taken into consideration.

Seeing their defeat, the Society notified its various homœopathic members, that they would be allowed three months of grace, wherein to repent or be expelled. Of course, these obstinate individuals paid no manner of attention to the notice, and when the Society undertook to carry out its threat, the question of their authority was carried to the courts.

It is perfectly plain, on reading the law in the case, that the Massachusetts State Society is so organised at present, that it cannot legally exclude these obnoxious members, and its attempt to do so proves how necessary it is for medical societies to remember that that they are not *extra legem*, as they seem to think.

Royal College of Physicians.

The Lectures of the present year will be delivered at the College, Pall Mall East, on each of the following Wednesdays and Fridays at five o'clock:—*Goulstonian Lectures*—Feb. 23, 28, and March 1, Dr. Hensley, "On the Mechanism of Respiration, Circulation, and Digestion." *Croonian Lectures*—March 6, 8, 13, Dr. Bristowe, "On Disease and its Remedial Treatment." *Lumleian Lectures*—March 15, 20, 22, Dr. Quain, "On Diseases of the Muscular Walls of the Heart."

United States Army Report.

The recently issued Annual Report of the Surgeon-General of the United States army gives the following statistics:—

Among the *white* troops, the total number of cases of all kinds reported as taken on the sick list was at the rate of 2,163 per 1,000 of mean strength. Of the whole number taken on sick report 54,710, or 1,863 per 1,000 of strength were for disease alone, and 8,797, or 300 per 1,000 of strength were wounds, accidents, and injuries of all kinds.

The total number of deaths reported was 17 per 1,000. Of 12 per 1,000 of strength died of disease, and 5 per 1,000 of wounds, accidents, and injuries.

The total mortality rate is greater than that for the previous year, the chief increase occurring in the proportion of deaths from disease. The proportion of deaths from all causes to cases treated was 1 death to 122 cases.

The reports from the *coloured* troops give the following figures, which do not include the white officers:—The total number of cases of all kinds reported was 3,551 or 1,362 per 1,000 of strength. Of these 2,954, or 1,137 per 1,000 of strength were cases of disease, and 587, or 225 per 1,000 of strength were wounds, accidents and injuries.

The average number constantly on sick report was 104 or 40 per 1,000, of whom 74, or 28 per 1,000, were under treatment for disease, and 30, or 12 per 1,000 for wounds, accidents, and injuries.

The number of deaths from all causes reported was 49 or 19 per 1,000 of strength. Of these 28, or 11 per 1,000 of strength, died of disease, and 21, or 8 per 1,000 of strength, of wounds, accidents, and injuries. The proportion of deaths from all causes to cases treated was 1 to 73.

Cundurango.

Dr. Bliss had great faith in Cundurango. Like many other Medical practitioners, says the editor of the *Pacific Medical Journal*, he deceived himself by hasty conclusions. He was led captive by appearances. This was an error of judgment, for which we may not condemn him. But he did more. He saw money in Cundurango, and came down from the professional curule to speculate in it and to advertise it, quack-like. He lost caste, as he deserved, and as all others will do who shall follow a similar course. And now he finds it expedient to resign his position as lecturer in the Georgetown Medical College, "for the benefit of the College." A good lesson is this for those Medical men who may be tempted to estimate the value of professional reputation on a specie basis. This is but one of the many condemnations that have appeared by our American brethren and we heartily echo them all.

Reproduction of the Membrana Tympani.

In the proceedings of the American Otological Society a case is narrated illustrating the almost complete reproduction of the membrane of the ear after its annihilation by disease.

The first Lady Doctor.

Anæsthesia has been traced as far back as the exsection of the rib in the garden; and now comes a writer in the *New York Medical Journal* claiming for Homer a knowledge of the art of embalming. When Patrocles, the friend of Achilles was slain, according to the Iliad, the body was washed and anointed with ointment nine years old, and laid on a bed and covered with fine linen from head to foot; and over all was spread a white mantle. The next day Thetis came and made a *post-mortem* injection into the body in order to preserve it, "and then she instilled into it through the nostrils ambrosia and ruby nectar, that his body might be uncorrupted." In quoting this the *Pac. Med. and Surg. Journ.* adds, Thetis would appear to have been the first female physician.

Failure of Calabar Bean in Tetanus.

In the *Philadelphia Medical Times*, Dec. 15th, is related a case of Traumatic Tetanus, arising from a pistol shot in the hand, treated in the Episcopal Hospital by Dr. Packard, in which calabar bean and chloral-hydrate were administered without avail. The case appears to have been a fair one as a test of the remedies, and to have enjoyed all the advantages which careful nursing could bestow.

Skin Diseases in India.

The Government are about to send to India for distribution a series of questions as to other diseases there which may possibly lead to a sort of supplement to the report on leprosy of the College of Physicians. The scheme has been drawn up by Dr. Tilbury Fox and Surgeon-Major Farquhar, and will probably lead to a valuoble report.

Two main objects are proposed:—1. To obtain and then to circulate a better knowledge of the more important endemic skin diseases of India, or such as principally attack the skin; and thereby—2. To bring about an agreement, which is far from existing at present, between the Profession in India and in England, as to the nomenclature, the typical character, the varieties, and the probable or demonstrated causes of the diseases in question.

It is believed that the inquiry may tend to show not only what are the diseases due directly to climatic influences, but the character and extent of variations in the same disease induced by differences of climate.

Amongst the diseases about which information is sought are Delhi boil, leprosy, the elephant leg, Malabar itch, prickly heat, the fungus foot of India, yaws, and Burmese ringworm.

Small-pox in Philadelphia.

The proportionate mortality in Philadelphia for the last eleven years, has been remarkably uniform from year to year, showing one death in 6·6 cases, or 15 per cent. The whole number of cases in that period was 14,952, and of deaths 2,242.

Physician Senators.

Four Italian Physicians have been chosen to be Senators of the New Kingdom. They are Professors Stanilaus, Cannizzaro, and Maggiorani of Rome, and Porta, of Padua. In the face of the example which has been set her by continental nations, it is incomprehensible why Britain should withhold from her distinguished children in the Profession of Medicine, the only distinction which can be said to be at all adequate to their deserts. Alive to the want of medical legislative ability in the House of Commons, the Government is about to create the office of Minister of Public Health, yet it refuses to reward the services which the public so gratefully recognise, and to strengthen the scientific power of the House of Lords by advancing Sir William Jenner to a well-merited peerage.

Pruritus of the Face as a Precursor of Small-pox.

Professor Crespi, of Bologna, says that a few moments' observation of patients who are in the incubative stage of small-pox will prove that they always suffer from an unpleasant sensation of itching about the face, especially on the forehead and chin. He has thus been usually able to diagnose small-pox in the earliest stages, and he believes the symptoms will be found to be uniform.

A new hospital is about to be opened in Capel street, Dublin. It is to be devoted to Midwifery and Ophthalmic Surgery. The first of these specialities being undertaken by Drs. T. M. Madden and J. A. Bryne, and the latter by Dr. T. Walshe, of Jervis-street Hospital.

Clerical Impertinence.

It is always a source of regret when a clergyman brings his order into public contempt by overbearing manners or impertinent interference with others. What can be said of the conduct of the Rev. Mr. Coke who, according to a report in the *East London Observer*, acknowledges that he took upon himself to refuse to allow the patients of Dr. Welch at the Queen Adelaide Dispensary to receive their medicines, because the doctor had attended at nearly 10 o'clock in the morning, instead of at 9! It appears that Dr. Welch has been the honorary medical officer for seventeen years, and that the conduct of the Rev. Mr. Coke has deprived the institution of his services, for as the committee did not repudiate the clerical interference Dr. Welch had no course open to him but to resign. This he has done, and thereby upheld the dignity of the Profession, which is grossly insulted by the clerical individual who has acted in this manner. We have no acquaintance with Dr. Welch nor with Mr. Coke, all our information coming from the *East London Observer*. We cannot say we have any wish to form the acquaintance of Mr. Coke, for it would be difficult to look upon a man who acts thus, as a gentleman, while how far his conduct is consistent with the Christian religion, of which we suppose by the prefix Rev. he is a professed teacher, might be safely left to the votes of the poor people who were denied the remedies ordered by the doctor. We think, however, that the case deserves the attention of the governors of the charity, to whom we therefore appeal to express their opinion of this clerical impertinence. Unpaid Medical service has indeed come to something if a meddlesome parson—who is, no doubt, in receipt of payment to teach Christianity—is to be suffered cruelly to deprive the sick of the aid afforded them by charity, and at the same time to insult a man who has given his services to those sick poor for seventeen years without fee or reward.

We observe that Dr. Munk is connected with this charity, and we hope that he will insist on an apology being offered to his ill-used brother. Such conduct as that of the Rev. Mr. Coke can but produce evil. We cannot by any stretch of imagination conceive of any excuse, and we should think that the residents of the district will not fail to make a representation to the bishop.

The clergy constantly make mistakes in public life by presuming too much on their office; but fortunately it is seldom that one hears of so gross a violation of all the rules of good breeding, or even of common decency.

Nitrite of Amyl and Chinese Samshu.

Dr. F. Porter Smith writes to the *Practitioner* for January, with reference to "the effect of nitrite of amyl" in causing flushing of the face, that Chinese 'samshu' (*i.e.* thrice distilled), or native corn-brandy, produces upon the people a remarkable reddening of the eyes and whole head, with a very evanescent excitement. This is due to the presence of fusel-oil (amyl-alcohol), and has exercised no small influence upon the drinking habits of the Chinese. The suffusion of the head and face immediately proclaims the fact of having drunk wine. The smell of the spirit, depending upon propylic and butyric as well as amylic compounds, acts as another tell-tale. Very strong and cheap spirit is easily obtainable in China, and may be used in the preparation of tinctures, due allowance being made for the presence of the amyl compound, which the Chinese distillers never remove by rectification. It acts like the salutary stink of gas, in giving timely warning of its near neighbourhood. Why remove fusel-oil from British brandy?

The Conjoint Examining Scheme for Ireland.

The meetings of the conference of Delegates from the "medical authorities," which for the last fortnight, continued to be held at frequent intervals at the Royal College of Surgeons in Ireland, have come to a conclusion, and as yet we are not in a position to make public the result of their deliberations, which, in the form of a report, will shortly be presented to the governing bodies of the various licensing authorities.

As far as we are able to give expression to the statements current in the profession in Dublin the result of the Conference appears to be eminently unsatisfactory. We are led to believe that the Universities have, so far as the Conference goes, secured protective clauses which would enable them to obtain for their students a narrower examination than is allowed to the students of Colleges. If this be true we neither hope nor expect that the scheme which may have been framed by this Conference will ever become law. The principle which Government adopted in its Bill—the only just and equable basis for a State examination—is rigid equality for candidates no matter whence they come. Once the supposed educational superiority of any student is recognised the examination ceases to be a free test, and endless questions arise as to the curricula and teaching of the favoured bodies. Without precise information we can say nothing, but we can lay down the principle that the Colleges of Surgeons and Physicians ought not to assent to any arrangement which regards their candidates as fit subjects for a searching test, but accepts the students of other bodies as half made practitioners and puts them through only an emasculate examination.

New Books in Medicine and Science.

Banks, Algernon C., The Vaccination Act, 1867 and 1871. With Introduction, Notes, and Index.

Arthur, Dr. R., Treatment and Prevention of Decay of the Teeth.

Testimonial to Dr. Hitchman.

On Thursday evening last, after the patients' weekly entertainment, Dr. and Mrs. Hitchman were invited to meet the officers and others connected with the Derby County Lunatic Asylum in the entertainment hall, and on their entering were received with much applause. The following address was then read:—

"TO DOCTOR AND MRS. HITCHMAN.

"We, the officers, attendants, nurses, and others employed at the Derby County Asylum, desire to convey to you, Dr. and Mrs. Hitchman, our heartfelt sense of your kindness to all during your superintendence of this Asylum. We beg to congratulate you on the high reputation this Asylum has gained under your superintendence during the past 21 years, and it is with deep regret we contemplate your removal from us, and the termination of your connection with the Asylum as superintendent and matron, which has been so beneficial and advantageous. We have heard with pleasure that you Dr. Hitchman, have been appointed consulting physician to this Asylum, and therefore foster the hope that at the annual entertainment and on other occasions both you and Mrs Hitchman will favour us with your presence. When we recall to mind your onerous duties since the formation of this Asylum, and the sympathy and encouragement given to us at all times, we feel that the institution and ourselves are about to lose valuable and tried officers. We thank you warmly far all past kindness, and ask you to accept this testimonial which we offer, and we pray that in your retirement you may be blessed with health and happiness for very many years."

The testimonial comprised an elegant bronze gilt drawing-room time-piece, bearing the following inscription:—"Presented by the Officers, Attendants, Nurses, and others, employed at the Derby County Asylum, to Dr. and Mrs. Hitchman, on their retirement, after 21 years' superintendence, as a token of esteem and respect."

Dr. Hitchman returned thanks in a feeling and impressive speech, and commented on the arduous duties all had to perform in connection with the insane, and which required for their proper discharge that those on whom they devolved should be actuated by true Christian feeling. He needed no testimonial to remind him of the valuable help he had received from many then present for a number of years in ministering to the afflicted, and acknowledged with feelings of gratitude the labours of those who had so ably assisted him in the management of the asylum since its opening, whose families had grown up and endeared themselves to him, and again thanked them for their kind wishes and elegant presentation.

Her Majesty the Queen has consented to become the patron of the Hospital for Consumption, Ventnor, which will in future have the prefix "Royal" placed before its present title. The second block of houses on the cottage principle, the corner stone of which was laid by H.R.H. the Princess Louise, will bear her name. Several princely gifts were announced at the annual meeting last week, which was a most successful one.

Reform of Inebriates.

The *Philadelphia Medical Reporter* says that the Washingtonian Home, in Boston, designed to assist inebriates who desire to reform, has been in successful operation for thirteen years, and during that period nearly four thousand patients have availed themselves of the privileges of the institution, and in a great number of cases men who had been given up by their friends as hopelessly addicted to intemperate habits, have been restored to respectability and usefulness. During the past year the number of patients under charge was two hundred and seventy-six, and the average cost of each amounted to forty-three dollars.

Small-pox in Utero.

Dr. Hampton, of Philadelphia, reports the following interesting case:—

I delivered a woman of a child suffering from small-pox. At the time of its birth the disease had reached the vesicular stage, showing that it had passed successfully through the macular and papular stages in utero. On the morning of the fifth day the pustular stage was reached. Up to this time, and until the morning of the tenth day, the child took nourishment and seemed to be doing well. On the morning following it vomited incessantly, blood gushing from its mouth and nose—the same evening it died. The mother was vaccinated successfully six weeks prior to confinement.

The Action of Quinine on the Blood.

The nature of the influence exerted upon the blood by quinine has been the subject of a fresh investigation by Schulte, reported in the *Neues Repertorium fur Pharmacie*, xx. 530, and of which some account appears in the *Pharmaceutical Journal.* Its extraordinary power of stopping fermentation and putefraction by destroying low organisms, such as bacteria and fungi, has been before pointed out. It is supposed to diminish the formation of pus in inflammation, by arresting the motions and preventing the exit from the blood-vessels of the white blood corpuscles, the accumulation of which, according to Conheim, constitutes pus. By depriving the red blood-corpuscles of the power to produce ozone, it diminishes the change of tissue in the body, and thereby lessens the production of heat. Ranke and Kerner have shown the waste of tissue is reduced when large doses of quinine are administered, as indicated in the smaller proportion of uric acid and urea secreted.

With the object of ascertaining whether this effect is referable to the direct influence of quinine or oxidation in the blood or to its indirect influence through the nervous system, Schulte employed a method based upon the changes occurring in the alkalinity of the blood, observed by Zuntz, who had noticed that a considerable formation of acid takes place in freshly-drawn blood, and continues in a less degree till putrefaction commences. The amount of acid formed was estimated from the diminished alkalinity of the blood, as comparatively shown by the quantity of dilute phosphoric acid required for exact saturation. A sufficient quantity of chloride of sodium was added to the phosphoric acid to prevent the blood corpuscles from being dissolved and interfering with the reaction by their colouring matter. The point of saturation was fixed at the transient reddening of carefully prepared test-paper by the carbonic acid. Schulte has thus been enabled to confirm the experiments of Zuntz and Scharrenhroich, showing that quinine and berberine lessen the production of acid, and that quinine can stop it both before and after coagulation; that sodium nitropicrate has an action similar to, and nearly as powerful as, quinine, while the action of cinchonine is much less energetic. Harley has shown that while quinine lessens oxidation in blood, some substances such as snake poisons, increase it. Binz found that when putrid fluids were injected into the circulation of an animal, the temperature rose; but that this increase of temperature could be more or less prevented by the addition of quinine to the putrid liquid, or the simultaneous injection of the quinine.

With respect to the influences of quinine on the change of tissue, Schulte gives the result of some careful experiments made by Zuntz, who found that after taking three 0·6 gram doses of hydrochlorate of quinine for two days the amount of urine he excreted was increased by one-third, and then decreased as much, the specific gravity falling from 1018 to 1012; the urea also showed a marked decrease.

The Carmichael Prizes.

These prizes, which are amongst the most valuable of any open to the Profession, are again offered by the Council of the Royal College of Surgeons in Ireland for competition. The prizes are of the value of £200 and £100 respectively for the first and second best essays, and will be awarded in May, 1873. The competitive essays must be on the following subjects:—1. The state of the Profession in its different departments, of Physic, Surgery and Pharmacy, in Great Britain and Ireland at the present time. 2. The State of the Hospitals and Schools of Medicine, Surgery and Pharmacy. 3. The state and mode of examination or of testing the qualifications of candidates of the different Licensing Colleges or Corporations, in Medicine, Surgery and Pharmacy. Full particulars will be found in our advertisement columns.

Tenia in a Newly-born Infant.

Dr. Samuel G. Armor, (*N. Y. Medical Journal, December*, 1871), describes a case of this kind, occurring in the Long Island College Hospital. An infant five days old was seized with trismus, and on the same day, under the operation of calomel and castor-oil, began to pass sections of tape-worm. Oil of turpentine and oil of fern were subsequently used, and the child recovered after discharging numerous joints of the worm. The mother, who had no symptoms of tenia, was treated with pumpkin-seed, two months after her confinement, and passed seventy segments of worm. The *Pacific Med. and Surg. Journal* remarks that Dr. Armor is as much perplexed, as he may well be, to ascertain how the animal got into the intestines of the fœtus in utero, as was a certain royal personage in regard to the apple in the dumpling.

Cod-oil—Pepsine—Pancreatine.

Many are the modes in which it has been endeavoured to aid the digestion of cod-liver oil. The subject is practically so often forced on all our readers that they may be glad to read the following from the *Pacific Medical Journal*:—

Every practitioner has been disappointed again and again in the failure to secure any benefit from cod-liver oil, in cases presenting the strongest *primâ facie* evidence of the adaptation of remedy to disease. Very often the oil remains unchanged in the stomach, and continues for many hours to rise in the mouth. Here it not only fails to do good, but is positively injurious by retarding digestion and destroying what little appetite the patient may have had. A lack of pepsine may cause this difficulty—the office of pepsine in regard to oily substances being, as far as appears, to dissolve the albuminous cell-wall, leaving the oil to be acted on, after it has passed from the stomach, by the pancreatic secretion. It is easy to replace the deficiency of the gastric juice by the administration of pepsine. But there may be another link in the chain wanting. The fatty granules require to be acted on by the pancreatic secretion in order to perfect a series of processes by which the oil is assimilated and rendered remedial. The pancreatic secretion may be deficient; and here the want may be artificially supplied by the administration of pancreatine. With or without reference to the cod-liver oil, those two substances are often very useful in feeble or disturbed digestion. We cannot always determine whether the stomach or small intestine is the seat of trouble, or whether both are implicated. If the stomach, pepsine may be the agent required, if the intestines, pancreatine. Experiment alone will settle the question. Often both are at fault, and here the two substances may be employed conjointly. It has been suggested to administer the pepsine first, and in an hour or two the pancreatine, after the pepsine has had time to do its work. But there is often trouble and uncertainty in this plan. There can be no reasonable objection to the inhibition of both together.

Pepsine is well known to the Profession, having been in general use for many years. Pancreatine is of more recent introduction, and has not been so extensively employed. We believe it is not properly appreciated. In our hands it has certainly done much good in certain cases of indigestion, or perhaps it would be better to say, of uncertain and irregular digestion, especially in persons of morbid nervous sensibility. It is particularly valuable in feeble digestion attended with occasional diarrhœa—cases in which the diarrhœa appears to be excited by the accumulation of undigested food, and in which it alternates with constipation or intestinal lentor. Here a tea-spoonful of Wine of Pepsine taken immediately before eating, and a tea-spoonful of Wine of Pancreatine half-an-hour or less after eating, will be often followed by the most gratifying results. Under this treatment anorexia will disappear and give place to appetite and enjoyment of food, and regular defæcation will be established, so that the annoying exhibition of aperients and astringents may be entirely dispensed with.

The ingenuity of pharmacists has devised a large number of preparations of undoubted excellence, combining not only the two agents above named, but bismuth also, and cinchona, and strychnia. The pancreas of the calf is the common source of supply, the juice being evaporated at a low temperature to a syrupy consistence and then mixed with dextrine and dried. This forms the powder called *pancreatine*, of which the different preparations are made. The principal preparations are Wine of Pancreatine; Elixir of Pancreatine; Syrup of Pancreatine; Troches of Pancreatine; Wine of Pancreatine and Pepsine; Elixir do.; the same with Bismuth; the same with Calisaya; Elixir of Pancreatine and Bismuth; Elixir of Pancreatine, Bismuth and Strychnia; Wine of Pancreatine and Pepsine. Other combinations have also been contrived, all of them possessing the properties belonging to the respective ingredients, and adapted to the most fastidious taste of both physicians and patients. A good preparation in the simple form is the Emulsion, which may be used in the same manner as the powder, as a basis for the various compounds; or it may be used in the simple form, though not pleasant to the palate in this way."

The editor in note says, "We are indebted to James G. Steele and Co., who are among our best pharmacists for a list of the preparations of pepsine and pancreatine manufactured by them, from which we have made the foregoing selection."

H.R.H. Prince Arthur has consented to preside at the annual festival, to be held in the spring, in aid of the funds of University College Hospital.

Following the example of Her Majesty the Queen, H.R.H. the Prince of Wales has distributed large quantities of game for the patients at the various metropolitan hospitals.

In the metropolis last week 1,423 deaths were registered, being 321 below the average. Consequently there was a great decline in the number of deaths from diseases of the respiratory organs.

Kelly, the Fenian, who was acquitted on the charge of murdering Talbot, on account of the legal question raised by the unsuccessful surgical operation of Dr. Stokes, was on Friday last found guilty of attempting to shoot Police-Constable Mullens when arrested, and sentenced to fifteen years' penal servitude.

A meeting of the Medical Society of the College of Physicians, Ireland, will be held in the College Hall, on this day, 14th February. The following business is set down on the notice paper:—1. Adjourned discussion on Dr. Burke's Paper. 2. Dr. Foot—on "Some observations on the treatment of Small-pox." 3. Dr. Lyons—on "Some statistics of Small-pox."

At the Polytechnic School of Vienna twenty-four females are now following the medical courses, and seven that of philosophy.

On the evening of last Monday week, Mr. Butcher entertained nearly a hundred members of the Medical Profession resident in Dublin and its immediate vicinity, at dinner in the Antient Concert Rooms. The assembled company included almost all the Hospital Physicians and Surgeons of Dublin, and a large number of its leading practitioners. Sir Dominic Corrigan occupied the right of the host, the President of the College of Physicians, Dr. Hudson, and Professor Haughton the seat on the left; and were supported by Dr. Banks, Mr. Porter and Sir William Wilde. The company were entertained after dinner by the admirable musical performance of the Glee and Madrigal Union. The health of Her Majesty and the Prince of Wales having been drunk, Sir Dominic Corrigan proposed the health of Mr. Butcher. In doing so he availed himself of the opportunity to urge upon the assembly the propriety and necessity for their assuming and maintaining an independent and outspoken position in political matters. He strongly urged upon them the consideration that the welfare of the Profession demanded from them a more manly, and definite policy than had yet characterised its members and he expressed his unqualified belief that it was a mistake to suppose that such a course could militate even remotely against professional success. The company did not separate till after eleven o'clock.

A MEETING of the Dublin Obstetrical Society will be held in the College of Physicians, on Saturday next, the 17th February, 1872. The following communications are set down for reading:—Dr. More Madden - On Spurious, Feigned, and Concealed Pregnancy. Dr. M'Clintock—On the use of a Hemp Saw for the excision of Polypi. Dr. Ringland—A case of sudden death seventeen days after delivery. Dr. Taylor—A Case of Cross Birth. Dr. Denham—On the use of Ergot of Rye. Dr. Atthill—On the treatment of some Inflammatory Affections of the Uterus.

THE handsome offer of £1,000 was made last June to the Royal Medical Benevolent Fund Society of Ireland, on the conditions that £2,000 be raised in donations of not less than £50 each, within a period of six months, and from Practitioners residing in Dublin. The friend who made this offer has since consented to extend the period to 1st July, 1872. The Central Committee being most desirous that such a substantial addition may not be lost to the funds of the Society, again entreat aid and co-operation. The following sums have been already given or promised:—

Dr. Banks	£50
Dr. Stewart	50
Dr. Kidd	50
Dr. A. J. Walsh	50
Dr. M'Clintock	50
John Hamilton, Esq.	70
Dr. J. F. Duncan	50
Dr. Head	50

◆

Literature.

LECTURES ON THE CLINICAL USES OF ELECTRICITY (a).

THESE lectures were delivered in 1870, at University College Hospital, and after being published in the *Lancet*, are now put before the Profession by the author in a separate form. They are strictly practical in character, and deserve to be read most carefully by all who desire to be able to afford to suffering patients some of the resources offered for the alleviation of diseases by the agency of electricity. Electricity is useful in practice both for diagnosis and treatment. If there be a decided difference in the electrical condition of two opposite limbs, there is clearly something wrong with one of them. Shamming may thus be detected in the case of railway accidents. Electricity may sometimes be able to cure a patient at once, as in hysterical aphonia; pain may be relieved or spasms removed, and paralysis arrested by its means. "There are other diseases which you cannot be said to cure, but which you may *relieve* by electricity. By its application you may, in many instances, again and again relieve pain or spasm, or slowly diminish and ultimately remove palsy. In these cases you assist, by electricity, the processes which lead to the removal of the pain, paralysis, or spasm; you put the patient, by electrical appliances, into a better position to improve, or be cured by the agencies of food, medicines, rest and time. Lastly, there is a group of cases in which, though you cannot cure, or even relieve, the symptoms, you may yet arrest the progress of the disease. Sometimes, for example, in a child with so-called *essential paralysis*, you may prevent deformity, though you cannot cure the paralysis. In certain cases of lead-poisining, muscular atrophy, &c., although you cannot reach the muscular substance, you may prevent any increase of the atrophy." After speaking of Franklinic electricity, the author speaks of Galvanism, or the forms of electricity developed by chemical decomposition. The only object a medical electrician has in choosing any particular form of battery, is to catch the electricity as best he may. This form is characterised by *low intensity* so far as regards muscles and nerves, but is considerable in quantity, and it produces chemical results, and results on temperature, "thermic results," that are not approximated by the Franklinic electricity. "What you want is a current that shall play evenly, and at a measurable strength, for a certain length of time. It is convenient to have a battery that is portable, and it is a great point to have one that does not require everlasting looking after." The contact battery of Weiss is easily portable.

Galvanism is used in two modes, one is continuous, the other interrupted current. The continuous current will relieve spasms of certain kinds, and pain of certain kinds. "A person may have a particular kind of headache; you pass a continuous current, as it appears, through his head, and sometimes in a few seconds the pain is gone. It will also remove some forms of tremor and of spasms." When weak, it produces little or no pain. The patient feels nothing or next to nothing. The current may be broken by dabbing one of the sponges on the limb, whilst the other is applied to some fixed point, or the apparatus may be used for making and breaking contact.

"There are," says the author, "two terms used commonly, and which you may see on batteries of various kinds, 'primary' and 'secondary.' It is for chemical purposes an almost useless distinction. The battery used in University College Hospital is known as Stöhrer's. With proper care, and but little trouble it acts well for many months; it can be put in action and out of action very readily, and its strength may be regulated with the greatest ease.

If you want to put into action a muscle which is in a state of morbid inactivity, either from some wasting of its own substance or some nervous weakness, you must apply, not a continuous, but an interrupted current. It may be a faradic or a galvanic current, the latter being interrupted by the hand, or by some mechanical apparatus. When on the other hand, muscles are contracting præternaturally, exhibiting spasms, either tonic or clonic, you may reduce this action by the continuous current, and also by a very rapidly intermitting faradisation. The electricity from whatever source obtained, may be applied, either to the bodies of muscles, or indeed single muscles, also through the skin, but by the nerve-trunks which pass to them. It is impossible to go into details of this important subject in the space allotted to us. Suffice to say that Dr. R. Reynolds' work should be read by all intelligent physicians.

◆

Sulpho-Carbolate of Soda in Scarlatina.

(*Transactions of the Medical Society of Pennsylvania.*)

"SCARLATINA," says Dr. J. B. Crawford, of Wilkesbarre, "occurred in almost every section of Luzerne county, varying much in severity in different cases and localities, but seldom evincing a marked malignancy of character. In addition to the better-known remedies, the sulpho-carbolate of soda has been used with very satisfactory results in the treatment. I take this occasion to strongly recommend its use to those practitioners who have not tested its efficacy in the treatment of this disease. In about thirty cases of scarlatina of average severity, I have relied almost exclusively upon this article, and have been highly gratified with the results. To a child of three years of age I would give one-and-a-half to three grains every two hours during the continuance of the more severe symptoms of the disease."

(a) "Lectures on the Clinical Uses of Electricity." By J. Russell Reynolds. Churchill, London. 1871.

Foreign Medical Literature.

DIAGNOSIS OF SYPHILIS FROM MICROSCROPIC EXAMINATION OF THE BLOOD.

(Translated from the *All. Wien. Med. Zeit.* for the MEDICAL PRESS AND CIRCULAR by DR. C. R. DRYSDALE.)

DR. LOSTORPHER (Medical Society of Vienna, 12th Jan. 1872) says that by using very high powers in patients with syphilis of Professor Leissl's clinique, and leaving the blood for three or four days, he constantly found little shining corpuscles in it. He found that these little bodies increased in size by budding (sprossenbildung). Hence arose new corpuscles, which again showed a proliferation by buds. This was so constantly observed by him, that by seeing these bodies he was enabled to diagnose syphilis with precision and certainty. He had had eight or nine trials given him by Prof. Stricker and Prof. Hebra, and each time he had rightly recognised from the preparations before him which was the blood of a syphilitic and which not. These bodies he calls syphilitic corpuscles. In some cases more than fifty such bodies could be seen in the field, in others fewer. These developed themselves often not before four or five days. He is not sure whether such corpuscles are newly produced in the blood by syphilis, or only allured by the disease. He related many cases of patients in the secondary and tertiary period of syphilis; and said it was curious that just as the anti-syphilitic remedies began to act, these bodies lessened in number and disappeared. Prof. Skoda praised the paper very highly, and observed that if prizes were given in Vienna, this paper deserved one. Prof. Stricker confirmed the observations of the author, and related the details of how the trials had been conducted. Prof. Hebra also confirmed the successful and extraordinary results of the trials spoken of by the author. This is quite a most remarkable and curious discovery, and will doubtless prove quite an era in the history of syphilis.

ABSCESS OF THE SPLEEN.

M. G. PELTIER, while giving his own views (a) on this rare form of disease, enumerates a long list of authors, and gives references to their writings in regard to it. From his observations we learn that although suppuration within the spleen may occur as an idiopathic affection, it is most frequently met with as one of the secondary accompaniments of pyæmia. In the idiopathic form the abscess may be recent or of old standing. In the recent, the cavity is filled with pale yellow pus, the sides formed by the tissue of the organ, whereas in that of long standing various kinds of alterations are observable. At first the sides of the abscess are smooth, and as a capsule; later that capsule undergoes absorption, the sides of the abscess approximate each other, and later still, all that remains is a depression, marking cicatrisation of the splenic tissues. Abscess of the spleen has little tendency to project towards the exterior, yet Portal states that cases are met with in which purulent collections have destroyed more or less of the tissue of the organ, so that only its tunics remained, forming a cyst distended by pus. Such abscesses, this anatomist observes sometimes produce sudden death, by their rupture into the cavity of the abdomen, two cases of which he has witnessed in persons reduced to a state of marasmus by slow fever, and others may happen in cases where during life the existence of depots of pus had not been suspected. They also sometimes evacuate themselves by the stomach (Coze), colon, left kidney, the cavity of the left side of the chest, the bronchiæ (Nass); at other times they discharge themselves among the parietes, their contents making a way for themselves along the abdominal muscles (Assolant) giving rise to numerous openings through which portions of the splenic tissue are discharged. In other instances they open into the loins, the pelvis, or are discharged by the vulva, as described respectively by Lomel and Schlichting. Sometimes adhesions exist between the surface of the spleen and surrounding tissues, diaphragm, stomach, abdominal parietes, liver, &c.

Etiology.—Inflammation of the spleen ending in suppuration, although a rare affection in temperate climates, is more frequently met with in hot and subtropical regions, and in some instances occurs without obvious cause. It may arise from a fall, a blow, or other injury; also from malaria, in connection with which it is mentioned by the majority of authors in intermittent fever. Some cases of it have moreover been met with in connection with typhoid fever, of which disease it has been looked upon as among the ordinary accompaniments, and one case has been recorded where it was attributable to a chill.

Symptoms.—In some cases there is no functional derangement present during life to indicate the presence of splenic abscess, which is only discovered after death, and although this is not always so, it is proper to observe that the symptoms are subject to great variety. After a fall, a blow, or other injury, the patient complains of pain and an abnormal sensation under the left ribs; by percussion the spleen is found to be enlarged, it is painful to the touch, and more or less severe pyrexia is present, often with nausea or vomiting. These symptoms may continue for a considerable time, and their ultimate progress is diverse. In some cases suppuration is re-absorbed, and after a time the symptoms disappear altogether; in others the affection ends in death, attended by some of the accompaniments of typhoid. During the progress of the disease the digestive functions may remain intact, notwithstanding that it is usually attended by nausea and vomiting. When an abscess forms we find that shivering takes place; towards evening the pulse becomes more frequent, and the temperature increases; sometimes the febrile indications assume an intermittent character, as of quotidian, tertian, or quartan, and in either case the occurrence of syncope is a dangerous complication.

Progress and duration.—The abscess may be absorbed, evacuated into the abdomen, or its viscera, or discharged through an external passage. In cases where it is emptied into the peritoneum death rapidly takes place; where it evacuates itself by the viscera recoveries are recorded as taking place, although the accounts of such are to be received with caution; and where the pus penetrates the parietes its evacuation by puncture is recommended.

Diagnostics.—Abscess of the spleen is to be distinguished from serous cysts and hydatids by the absence of pain in the latter, their slow rate of increase, there being no fever, and no disturbance of the digestive functions; from cancer, by the completely different progress. With regard to encysted abscess between the spleen and the diaphragm, these impede the respiration considerably, and would appear to be always fatal. Among the affections most difficult to be distinguished from splenic abscess are those of the kidney, especially cysts and abscess, although the seat and character of the pain, and examination of the urine will generally remove all doubts on the subject.

Treatment.—When the measures adopted have been ineffectual in checking suppuration quinine should be freely administered, in order to prevent, if possible, or at any rate diminish, the severity of the febrile accessories. If the diagnosis has been made with certainty steps may be taken to evacuate the pus with some hope of success, and as have been used by MM. Eloge and Roubaix. Having by means of caustics applied externally, produced adhesion between the spleen and the abdominal parietes, an exploring puncture is then made into the viscus, and in the event of pus being detected an incision should be made for its escape. A seton then introduced into the wound should be left some time, and the discharge of the contents of the abscess encouraged by means of poultices.

(a) *La Mouvement Medical*, 7th January, 1872.

The spleen is like other organs, liable to become the seat of metastatic abscesses as cases of pyæmia. In *purulent affections* is blackish, mottled, softened, and interspersed with abscesses, chiefly in the exterior of the organ, as when they occur also in the interior the former are the most numerous, although, according to Braidwood, such abscesses exist most frequently in the interior. These deposits are seldom single. They are almost invariably multiple, numbering on some occasions five, six, and upwards. Their size varies from that of a pea upwards. In some instances the pus is simply infiltrated in the splenic tissue, in others the deposits are enclosed in a false membrane. As regards their manner of formation, they are referred by different authors to effused blood, which demands a nucleus for suppuration, the fluidity of the blood being a result of its morbid alteration; to simple deposit of pus, and to the existence of phlebitis. At present, all are agreed that in pyæmia the blood is altered by pus, but phlebitis is alone insufficient to explain the production of metastatic abscesses. The greater number of recent observers consider that they are produced as results of embolism caused by fibrinous detritus in the circulation. The presence of abscesses in the spleen is less to be detected by the presence of pain than by the size and substance of the organ by manual examination, and by the presence of the other symptoms of pyæmia. When such metastatic abscesses exist, whether in the spleen or in other organs, the prognosis is of extreme gravity, and it is seldom that a fatal issue is prevented. As to the treatment, the measures recommended are repeated purgatives and the employment of quinine, to these should be added some tonics, and the improvement of hygienic conditions.

◆

Correspondence.

SIR WILLIAM GULL ON MEDICAL SCIENCE.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I am surprised to find that you have taken no notice of the extraordinary address delivered by Sir W. Gull at the last meeting of the Clinical Society of London. Possibly the fact of his admitting that it was unprepared has induced you to allow its marvellous statements to pass without comment; but although under some circumstances a dignified silence has its advantages, there are seasons when it is well to be outspoken, and such, I imagine, are the seasons when one who is generally accepted as representing the whole of our Profession, gives expression to views which are either peculiar to himself, or held by a very small minority. Especially is this the case, when the speaker is a man who is now so justly popular.

Not only are Sir William's views totally opposed to the spirit of the Christian religion, but unless I am greatly mistaken they are in glaring conflict with common sense too. Indeed, he seems instinctively to feel that this is so himself, for after saying that "Disease in its essential nature depends on processes so identical with those which underlie the normal phenomena of life, that could it be regarded apart from the conditions of comfort or discomfort, disease could hardly be said to exist," he candidly adds, "But if we were to tell the public that there was no such thing as disease, we should hardly be believed," which is certainly very true.

No reasonable man will deny that diseases of all kinds, whether physical, mental, or moral, consist of some *perversion* of normal processes; but surely it is altogether a retrograde movement in science to assert that such perversions are brought about otherwise than *ab extra*. We may class all such theories with that of spontaneous generation, which has long since been exploded. That certain diseases, or what at least the general public seem pretty determined to regard in the light of diseases, are the result of something *ab extra*, we all very well know. I need only instance the contagious fevers, especially small-pox, which by inoculation we can induce at will. And although diseases (or perverted normal processes) sometimes come to light in the individual without any apparent external cause, it is surely very unphilosophical thereupon to use language implying that such perversions could at any time (however remote) have arisen spontaneously. Sir William Gull, however, says that "the beginnings of disease must be sought in a series of processes extending so far back that they can hardly be said to have a beginning!" Commend me to the book of Genesis, which, whatever its shortcomings in a scientific point of view, is at any rate philosophical enough not to assert that anything which in the first instance was *normal*, or "very good," could be perverted without the introduction, *ab extra*, of some perverting influence. It puzzles one to know how any microcosm, all whose parts are harmonious, and the cycle of whose actions is perfect, can ever get out of order of itself. But suppose some deleterious influence from without, and the matter is soon explained. The entrance of some perverting influence is that which causes disease in the first instance, and all causes being ceaseless in their operation, their immediate effects becoming the causes of their subsequent effects *ad infinitum*, we can easily understand how abnormal conditions (especially those affecting vital structures) are transmitted from generation to generation. But although I am ready to admit that upon the entrance of the perverting influence, the processes carried on in the system, continue as nearly normal as possible; nay, although I will go further, and say that much which seems to aggravate the mischief is in reality an effort on the part of the affected organism to be rid of the offence; still, I cannot conscientiously call a spade other than a spade, or disease other than a most grievous ill, out of which God only can bring good.

Trusting that I have not been guilty of unwarrantable presumption in daring to criticise the utterances of one so eminent, and begging you to insert my communication in your next (under protest if you please),

I am, Sir, your obedient servant,

D. B.

Kingston-on-Thames, 7th Feb., 1872.

◆

Medical News.

H.R.H. The Prince of Wales arrived at Windsor from Sandringham on Saturday, having borne the journey remarkably well. On Monday he started with the Princess for Osborne, where Her Majesty was waiting to receive them.

The London Fever Hospital.—On Friday last the annual meeting of the Governors of this institution, was held at the Freemasons' hall. The Chairman, Mr. Lumley, referred to the peculiar interest which attached to the meeting this year in face of the untoward event of the illness of H.R.H. the Prince of Wales who has for a long time past been patron of the institution having been attacked with one of those fevers which were treated in its walls, and it was a remarkable fact that one of the highly skilled physicians who had attended upon the Royal patient was some years ago, a physician administering to those occupying its beds. He passed on to speak of the great interest the Prince had always shown in the hospital, an interest the more marked from his recommending it, during his convalescence, for the thank-offering of Mr. Readymoney, the Parsee of Bengal, a recommendation which brought the welcome addition of £200 to its funds. The speaker then referred to the change which had been made in the character of the institution through the legislation of 1867, which had entailed upon the metropolis the duty of providing for pauper fever patients in separate asylums. Now, therefore, the institution would wholly revert to the intention of its original foundation—as a place where contagious diseases of the classes above pauperism might be treated, and, in addition, a space would be set apart for the accommodation of members of the superior classes of society who might contract a disease of the character treated here, and would desire to remove from their households the means of contagion. The report of Dr. Broadbent showed that typhus fever had been lessened, that relapsing fever had only slightly occurred, and that typhoid had diminished. Votes of thanks were passed to Dr. Broadbent, the visiting physician, to Mr. Hugh Owen, the hon. secretary, and to the committee of management. A vote of congratulation to the Prince of Wales, and of thanks for a present of game, having been agreed to, the Dean of Westminster, Sir Bartle Frere, and Mr. Readymoney were elected vice-presidents. A vote of thanks to the chairman concluded the proceedings.

The Duchess of Saxe-Meiningen, her Majesty the Queen's niece died on Saturday last from an attack of scarlet fever.

As we were going to press a report reached us of the assassination of Lord Mayo, the viceroy of India, by the hands of a convict. We hope the report is without foundation.

The Medical Society of London.—At a meeting of this old society especially convened for the purpose, it was decided that the following congratulatory address should be presented to Her Most Gracious Majesty the Queen. "We, the President, Council and Fellows of the Medical Society of London in special meeting assembled desire to approach your Majesty with feelings of deep thankfulness to give utterance to our humble and earnest congratulations that it has pleased the Almighty to raise up His Royal Highness the Prince of Wales from a bed of sickness, and thus to avert from your Majesty's House, and from your Majesty's loyal people, a calamity, of which the possibility had filled all hearts with apprehension. We rejoice that it has been the privilege of honoured members of our own calling to be the instruments under Providence, by which this great blessing has been conferred upon the nation; and we pray that the great disposer of the issues of life and death may extend his continued protection to your Majesty and to his Royal Highness, and that your Majesty may long reign over a devoted and loyal people—Signed on behalf of the Council and Fellows of the Society, Andrew Clark, M.D. President—George street, Hanover square, London, January 20th, 1872."

Sanitary Inspection of Shipping.—A deputation of the Thames Shipping Inspection Committee, with Dr. Letheby, Dr. Dickson, and Dr. C. Meymott Tidy, hon. sec., waited on the President of the Local Government Board on Thursday, to urge the advisability of a clause being inserted in the new Sanitary Act sanctioning conjoint action amongst the several boards and vestries abutting on the Thames, for the purpose of carrying out a complete inspection of the shipping in the river and in the docks, and sanctioning the raising of the necessary funds by the several authorities. The attention of Government was promised.

Royal College of Surgeons of England.—At a meeting of the council, on Thursday, Mr. Le Gros Clark, F.R.C.S., senior surgeon to St. Thomas's Hospital, was elected an examiner in dental surgery for a period of five years. The following gentlemen were nominated to fill the vacancy in the court of examiners caused by the resignation of Mr. Cock—viz., Mr. John Birkett, of Guy's Hospital, Mr. Spencer Smith, of St. Mary's Hospital; Mr. Campbell De Morgan, of Middlesex Hospital; and Mr. Callender, of St. Bartholomew's Hospital.

Naval Assistant Surgeons.—The following is a list of naval medical candidates who were successful at the competitive examinations held at London in August, 1871, and at Netley in February, 1872, after having passed through a course at the Army Medical School, Netley, and who have received commissions as assistant surgeons in her Majesty's navy:—F. A. Nixon, 4,471 marks; J. H. Anderson, 4,451; C. P. D. Chittenden, 4,385; C. Davidson, 4,155; W. B. Drew, 3,821; W. H. Elmes, 3,650; C. E. Gray, 3,620; C. Feltham, 3,460; W. R. White, 3,455; R. G. Brown, 3,443; J. M'Carthy, 3,342; W. C. Sandys, 2,945; G. J. Gray, 2,915; H. M. Levinge, 2,890; R. W. Brereton, 2,473; J. Simms, 2,468; J. Donovan, 2300.

Pass List of the Army Medical School.—The Director General presents his compliments to the Editor of the MEDICAL PRESS, and begs to enclose for insertion a List of Candidates of her Majesty's British Medical Service, who were successful at the competitive Examinations in August last, and who have passed through a course at the Army Medical School.—E. W. Cottle, studied at Oxford and London, number of marks 5,118; R. V. Ash, London and Aberdeen, 4,625; P. S. Connolly, Dublin, 4,510; C. E. Dwyer, Dublin, 4,447; J. G. Rogers, Dublin, 4,445; W. A. D. Fasken, London, 3,993; B. B. Connolly, London, 3,927; J. D. Edge, Dublin, 3,866; F. E. Barrow, London, 3,837; R. Blood, Galway and Dublin, 3,797; H. J. W. Barrow, London, 3,703; W. P. Bridges, London, 3,695; R. Drury, Galway and Dublin, 3,694; W. C. Grant, Dublin, 3,654.

Ligature of the Subclavian Artery.

THE *Australian Medical Gazette* extracts the following analysis of 250 cases of ligature of the subclavian artery from a valuable paper published in the *Archives für Klinische Chirurgie*:—

In fourteen cases the vessel was tied internally to the scalenus muscle; in four of these, the common carotid was tied at the same time. Death ensued in all the cases—in three, from accidents during the operation, such as injury of the trachea and the pleura; in the others, from secondary hæmorrhage. In all the cases in which an after-death examination was made, the vessel was not obliterated, although a fibrinous clot was found near its centre.

In thirteen cases in which the vessel was tied between the scaleni muscles, in six the operation was successful, in six unsuccessful, and in one case the result was not known. He considers that the operation performed in this part of its course presents great advantages in aneurism of the axillary and subclavicular regions from only two deaths occurring in seven cases, while seventeen out of twenty-five died when the vessel was tied externally to these muscles.

In 183 cases in which the vessel was tied externally to the scaleni, in one it was for aneurism of the thoracic artery, two for the innominata, twenty-five for the subclavian, sixty-nine for the axillary, nine for the brachial, seventy-four for cases of hæmorrhage, five for tumours, three as a preliminary operation to amputation of the arm or the removal of tumours, and in five for unassigned causes.

It was practised in 163 males, but only twelve times in females, eighty-three times on the right side to sixty on the left.

In five cases the vessel presented anomalies in its course.

The accidents occurring during the operation were opening the pleura, wounding the aneurism, ligaturing the nerve along with the vessel, ligaturing the anterior scalenus muscle, entrance of air into the subclavian or jugular veins, and wounding the phrenic nerve.

In twenty-three cases the temperature of the limb after the operation was noted. In six it remained the same as before the operation, and the same as that of the opposite limb; in three cases it remained so throughout, but in one it rose on the second day, and in one it diminished on the side operated on.

In fourteen cases the temperature declined in a marked manner, in from three hours to four days after the operation. In only three cases did the temperature rise immediately after the operation; in two of these it continued until the fourth day. The ligature came away in one case on the fifth day, two on the seventh, one on the ninth, six on the eleventh, six on the twelfth, three on the thirteenth, three on the fourteenth, four on the fifteenth, five on the sixteenth, seven on the seventeenth, four on the eighteenth, two on the nineteenth, five on the twentieth, ten from the twentieth to the thirtieth day, and in six from the thirtieth to the eightieth. On the fourth day the pulsation generally returned in the vessel, but in one case it did not return for six months. The pulsation in the radial artery, in one case, was not arrested for an instant.

The cause of death found in sixty-eight cases out of 100 which died, were—fainting, nine; cerebral effusion, one; gangrene of the limb, three; pleurisy and pneumonia, five; pneumo-thorax, two; pericarditis, one; inflammation of the sac, three; rupture of the aneurism, one; pyæmia, eleven; hæmorrhage, twenty-nine; ligature of the nerve and vein, one; ligature of the nerve instead of the artery, two.

The statistics showed the mortality to be fifty-one per cent.

In ligature of the artery below the clavicle he found that, out of forty-seven cases, in four the operation was not completed, and in one acu pressure was used; in twenty-six cases of aneurism, thirteen were cured, twelve died, and one was uncertain. In nineteen cases of hæmorrhage, four recovered, eleven died, and four were uncertain.

Treatment.—He states that, of 133 cases, in thirty-two of which there was no attempt made at an operation, three were cured spontaneously, and twenty died. The others were lost sight of.

In twenty-three cases, in which Valsalva's plan—compression, manipulation, galvanic puncture, injection of perchloride of iron, &c., was used, eleven were cured, six were but little benefited, and six died

The following were the results of the ligature applied to the peripheral aspect of the aneurism:—In six in which it was applied to the common carotid, three were relieved, and three died; in one to the axillary artery, the result was not known; in four to the subclavian, below the clavicle, four deaths; in seven external to the scaleni muscles, four deaths and three cures; in one internal to the scaleni, death.

In the case in which the ligature was applied near the centre of the sac, external to the scaleni—twenty-three cases—sixteen deaths and seven cures; between the scaleni—five cases—two deaths, three cures; internal to the scaleni—ten cases—ten deaths. Out of twenty cases in which the arteria innominata was tied, only two were cured.

NOTICES TO CORRESPONDENTS.

"HINDU VIEW OF CHOLERA."

To the Editor of "The Medical Press and Circular."

Sir,—You did me the honour in your Journal of January 31st, to notice my pamphlet entitled "Hindu View of Cholera," published by Curtice & Co., 13 Catherine street, Strand.

Your reviewer selected a few detached and partial sentences, and with the successful result of drawing a picture of ridicule.

No work or essay ever written, whether of the greatest or least value, but so treated, might be with equal ease made to appear worthless.

I had always heard that the Medical Press and Circular had a character bolder, larger, and less clerical than other medical journals. I was therefore surprised at the scope of your review.

Whether my ideas are on a true or false method, the future only can decide; I may fairly say that I have hardly received justice in the picture you have drawn.

I should not quarrel with your opposing my views; but I do complain that your notice does not fairly represent me to your readers.

I hope you will do me the honour to insert this reply.

I am, &c.,
Golaub Sing, M.D.

MEDICO-PARLIAMENTARY INTELLIGENCE.

Notices of motion of the following Bills were given at the opening of the Imperial Parliament last week:—

CONTAGIOUS DISEASES.

Mr. BRUCE gave notice that he should bring in a bill for the prevention of certain contagious diseases, and for the better protection of women.

THE CONTAGIOUS DISEASES ACTS.

Mr. W. FOWLER gave notice that he would bring in a bill to repeal the Contagious Diseases Acts of 1866 and 1869.

PUBLIC HEALTH.

Mr. HIBBERT, in the absence of the President of the Local Government Board, gave notice that that right hon. gentleman would, on the 16th inst., bring in a bill to amend the law relating to public health.

UNIVERSITY OF DUBLIN.

Dr. L. PLAYFAIR (moving for Mr. Fawcett) obtained leave in Committee for the introduction of a Bill to abolish tests in, and alter the constitution of, the University of Dublin.

ALBERT MEDICAL INSURANCE COMPANY.

Mr. S. CAVE obtained leave to bring in a Bill authorising inquiries into the causes of failure in the above company.

INFANT LIFE PROTECTION.

Mr. CHARLEY obtained leave to bring in a Bill on the above subject.

Communications have been received from:—Mr. Erasmus Wilson. Dr. Letheby. Deputy Inspector-General Dr. Gordon. Dr. Golaub Sing, London. Mr. Henry Lee. Dr. Waters, Chester. Dr. Fox, Scarborough. Dr. Cotterell, Westbromwich. Mr. Hutchings. Mr. Tait. Dr. Mitchell. Dr. Murphy, London. Dr. J. Smith, Bishops Lydeard. Mr. Tichborne, F.C.S. Dr. Edmunds. Mr Courtenay. Dr. Williams, Malvern. Dr. Johnson, London. Mr. J. Sloane, Forest Row. Dr. McNab, Epping. Dr. Morgan, Dublin. Dr. Barr Meadows, London. Dr. Mapother, Dublin. Mr. Hanslip Seis, Epperstone. The Secretary of the Royal Society. The Director-General of the Army Medical School. Dr. Townsend, Miltonen, Malbay. Dr. Haddon, Horncastle. Dr. Tulton, Saintfield. Dr. Thorowgood, London. Dr. Cahiel, Kells. Dr. Royes Bell, London. Dr. Reynett, Portlaw. Mr. G. E. Bell, Morecambe. Dr. Kidd, Armagh. Dr. Welch, Hackney, Dr. Murray, Tobercurry. Mr. Biddle, Kingston-on-Thames. Dr. Cardiff, Ballenab[illegible]ola. Dr. Brett, Notting hill. Dr. McIntire, Coleraine. Mr. J. L. Milton, London. Dr. Hawthorne, Dromore. Mr. Moore, Hastings. Dr. Landels, Lisnaskea. Dr. Micke, Ripon. Dr. Wolseley, Dunfanaghy. Mr. W. Hyslop, Church Stretton. Mr. Fisher, Portarlington. Mr. Wilson, Brookboro'. Mr. Harrison, Roscommon. Mr. Cooke, Enniscorthy. Mr. Rankin, Kirkcubbin. Mr. Madras, Dripsey. Mr. Fitzherbert, Navan. Dr. Meehan, Kilmallock. Dr. Smith, London. Mr. Croker, Limerick. Dr. O'Keefe, Mallow. Dr. Courtenay, Drogheda. Dr. Burke, Thurles. Dr. Frier, Waringstown. Dr. Harvey, Derry. Dr. Mullally, Templemore. Dr. Taylor, Ferns. Dr. Dale, Plymouth. Mr. Collenette, Guernsey. Dr. Chambers. Dr. West, &c.

To the Editor of the "Medical Press and Circular."

Sir,—1. Does the licence of the Apothecaries' Company, London, entitle its holder to compound prescriptions and sell medicines in Ireland? 2. Does the licence of the Apothecaries' Hall, Dublin, entitle the holder to compound, &c., in England? N. E.

5th February, 1871.

[The holder of an English or Irish Apothecaries Licence is legally incapacitated from practising in the other country, but we believe the possession of home qualification is not enforced by either body, but that, on the contrary, every facility is afforded to Licentiate Apothecaries who are anxious to obtain the legal right to practise in the country which they have selected.—Ed. M. P. & C.]

The Sad Sequel.—In our last number we drew the attention of our readers to the melancholy death of Mr. F. B. Eaton, Surgeon, of Nuneaton, stating that we should be happy to receive and acknowledge subscriptions, however small, towards the fund being raised for the benefit of his widow and family, who were totally unprovided for. We regret that our appeal has met with so little success, that the only sum we have to announce—which we do with many thanks—is from Dr. Barr Meadows, of Dover street, London, as "a mite towards the Eaton Fund." £1 1s.

The following Articles, &c., in type, are unavoidably held over:—
Mr. E. Hamilton, "On Excision of the Knee-joint."
Dr Shiel, "On the Influence of Ergot in Midwifery Practice."
Mr. Bo lean, "On Contract Drug Purchasing."

LECTURES ON DERMATOLOGY.

Delivered in the Royal College of Surgeons of England, in February, 1872, by

Erasmus Wilson, F.R.S.,

Professor of Dermatology to the Royal College of Surgeons of England.

Lecture I. (*continued from page* 136).

No. 93 is a beautiful example of the prominent variety of erythema, occurring in the form of a diffused blotch several inches in diameter, and would scarcely be recognised as belonging to the papulous group were it not for the presence of isolated papules around its circumference. It is highly characteristic of the affection, its scarlet and lilac hues, its slight but obvious prominence, its sharply defined and tumid border, and the absence of all lesion of the skin beyond the mere hyperæmia. It is true to the nature of the parent affection in appearing on a joint, and it already shows indications of subsidence within the area, and presents the purplish tints of decline. We are informed that it made its first appearance suddenly, that it was accompanied with tingling pruritus, and that in twenty-four hours the redness vanished, leaving behind it a pale orange stain, like that of a bruise, which remained visible for several days.

The patient was a young woman, twenty-four years of age; she had suffered severely from a painful confinement with serious complications, had been kept in bed for three months, and towards the end of that period had an attack of constipation, with headache and feverishness. Concurrently with these symptoms, the present eruption made its outbreak on the knees, ankles, and arms. No doubt, the erythema acted as a derivative upon the constitutional disorder, and a mild aperient would have been the therapeutic method of dealing with both.

The tuberous forms of erythema, namely, erythema tuberosum and nodosum, are more chronic in their nature than erythema papulosum; they, however, take their origin in a similar cause, disorded digestion and assimilation, and are commonly met with in the extremities, more especially in the lower limbs.

Nos. 94 and 95 are casts in plaster and wax of the leg of a young woman, a domestic servant, aged twenty-two; she had recently come to service in London from the country; her digestive organs were deranged; she had headache and feverishness, and, as a consequence of this state of constitutional disorder, painful, red, tuberous spots appeared on the legs; the redness of the spots, unlike No. 93, faded towards the circumference; the prominence was less obvious to the eye, but was distinctly felt in the skin, apparently sinking deeply into the tissues; they lasted for a week or ten days, and when the redness and hardness disappeared, yellowish stains, with slight ecchymosis, were left behind. Erythema tuberosum, therefore, although of the same nature, would appear to affect the tissues more deeply than erythema papulosum; and, as a consequence, the neurotic manifestations would correspond with the depth of the nerve affected, producing pruritus in the superficial, and soreness and aching in the deeper affection. The treatment in this case was a few days' rest in bed, a mild purgative with salines, and subsequently quinine and sulphuric acid—the girl being feeble and delicate in constitution.

Erythema nodosum agrees in general character with erythema tuberosum, but is commonly oval in figure, occupies the limbs, especially the lower extremities, is redder, more painful, more prominent and profound, lingers for a longer period, and leaves behind it at its decline a deeper stain, and very often a decided ecchymosis. The long diameter of the swelling usually corresponds with the axis of the limb, but the casts in plaster and wax numbered 96 and 97, exhibit an erythema nodosum which crosses the limb, and surrounds the lower part of the leg like a bracelet. The patient in the latter case was a woman, forty-five years of age; digestion and assimilation were bad, she was a good deal debilitated, and the swelling extremely painful. Erythema nodosum is usually isolated, and the number of its prominences few —in the instance under consideration it was solitary.

Erythema admits of a very natural division into four principal groups, for example,—fugitive, fixed, migratory, and tumescent. The papulous, tuberous, and nodose forms which we have just been considering belong to the tumescent group, in consequence of their prominence or depth; while the specimens 98 and 99 are essentially migratory, originating in a given spot, and dispersing centrifugally by the circumference so as to produce a ring, and preserving a border of moderate breadth. This is the class of migration which is termed serpiginous, and one which is met with very commonly in affections of the skin. I have had occasion to notice it already in connection with eczema and lichen, and we shall come to it again in subsequent groups, more especially in roseola, syphilis, lepra, lupus, epithelioma, and still more strikingly amongst affections of the follicles. It may be stated therefore to be one of the phenomena of the pathology of the skin, to sweep along the surface like a ripple or a wave, to depart from a centre and spread by the circumference while the central area is in the condition of recovering its normal state and appearance. The Natural Philosopher has acquired more than one useful lesson from throwing a pebble into a tranquil pool, and observing the ripple that seems to flee from the point of concussion of the liquid element; so, from the same experiment, the Philosopher of Medicine may deduce the law which governs the formation of a circle around a central point of morbid action in the skin, and most strikingly so in the curious example of centrifugal erythema which is illustrated in the specimens, Nos. 100 to 103.

We have already perceived a tendency to growth by the circumference in specimens Nos. 91 and 92, but in the case of No. 98, eccentric development is a predominant character. The illustration is termed erythema roseolosum, on account of its colour, and to distinguish it from the more efflorescent erythemata which have already received the names of circinatum, gyratum, and marginatum. It must not, however, be supposed that these terms apply to actual differences in the eruption, for, in fact, they simply distinguish modes of manifestation and growth. When the circles are moderate in number they retain their circinate form; when they are numerous, and meet in their growth, and break up into arcs of circles, which retain an appearance of continuity of figure of a complex description, the term "gyratum" is applied to the eruption; and when a few arcs of circles remain standing alone in a state of chronic hyperæmia, the rest having vanished, the case is one of erythema marginatum. In brief, the isolated circles are termed "circinatum;" the tracery resulting from the confluence of a number of circles, "gyratum;" and one or more arcs of large circles in a chronic state of hyperæmia, "marginatum."

The patient whose leg is represented in drawings Nos. 98 and 99 was a lad, twelve years of age. He had been exposed to over exertion in the spring of the year. On the following day the eruption made its appearance in the form of circular rose coloured spots, with a pale centre, and soreness, tingling and smarting, comparable to the stinging of nettles, while a hot bath converted the spots from a bright rose red to a purple hue. From the first, a sudden differentiation of area and border made itself evident, and the border quickly assumed the annular character, and was slightly prominent, while the area subsided in elevation, and faded in tint of redness. The eruption reached its height on the fourth day, and then rapidly declined, leaving behind it purplish-yellow, bruise-like stains.

Nos. 100, 101, and 102 are examples of an erythema developed in the form of an erythema papulosum, and throwing out a prominent ring from its circumference, without any subsidence of the centre. Hence, we are enabled to distinguish in the figure of the eruption a central boss and external ring, and are reminded of the iris of the eyeball. This resemblance has gained for the affection the name of erythema iris. In constitutional and therapeutical relations, as also in seat of development, it differs in no respect from ordinary erythema papulosum, but is interesting, pathologically, not only in reference to the primary suspense, and subsequent renewal of the hyperæmic congestion, but also because it constitutes a link to more decided forms of eccentric annulation, which we shall have to pass in review at a subsequent period.

Gastric disturbance may be said to be at the root of all the examples of erythema which we have hitherto examined; and the cause of such gastric disturbance would seem to be of little or no importance. One form of this group of affections, namely, urticaria, is known to arise from articles of diet, often of the most innocent kind; and an attack, generally severe, occasionally follows the use of mussels as an article of food. With such facts before us, we are prepared to recognise the influence in eruption—production of other substances introduced into the stomach in the character of medicines; for example,—belladonna, which produces an erythema; iodide of potassium, which causes a papular folliculitis; arsenic, which gives rise to an erythema of the skin, erythema arsenicale; and the balsam of copaiba which also excites an erythema, taking its origin in the follicles.

When we observe the primary effect of the substance to be a folliculitis, a something acting on the glandular element of the skin, we may be led to infer that the action thereby excited is eliminative, and that the folliculitis really represents an effort on the part of the glandular apparatus to cast off a poisonous or irritative material present into the blood. But it is equally evident that the follicle is the most easily approached and most vascular portion of the skin, and, therefore, that an irritative action would be excited within its walls more quickly and intensely than on the papillary stratum of the superficies of the skin. With the latter view I am myself disposed to concur; and I look upon the action of iodine, arsenic, and copaiba on the skin as an illustration of simple irritation, or possibly of over stimulation of the cutaneous tissues.

Another observation which would seem to confirm this conclusion is the well-ascertained therapeutical effect of arsenic and iodine upon the skin. Arsenic as a cutaneous stimulant or tonic is capable of curing many chronic affections of that organ, and the specific influence of the iodide of potassium is equally well recognised in the cure of syphilis of the skin. The balsam of copaiba administered as a curative agent in chronic inflammation of the genito-urinary mucous membrane is also known in some instances to occasion erythema of the skin; and the accidental cure of lepra vulgaris during the administration of the balsam of copaiba for such a purpose led an eminent French dermatologist, Hardy, to the recommendation of copaiba as a treatment of lepra. The remedy has not been in use sufficiently long to determine its usefulness, and my own experiments have not given me results which I can regard as favourable to its success.

The model, No. 105, is an example of an erythemata which may be termed "copaibicum," and which is doubly interesting to English surgeons from its comparative rarity amongst ourselves. It is constituted of papulæ and maculæ of a bright crimson colour; the papulæ represent inflamed follicles, and the maculæ, which are punctuated in the centre, that portion of the vascular stratum of the corium which immediately surrounds the follicles; sometimes the macula is elevated in the centre so as to constitute a papuli; and, on different parts of the model, maculæ will be observed to be coherent, sometimes in small blotches, and sometimes in rings.

EYE DISEASES AND INJURIES.

A Course of Lectures

DELIVERED IN THE

CITY OF DUBLIN HOSPITAL,

By Archibald Hamilton Jacob, M.D. Ed., F.R.C.S.I.,
Ophthalmic Surgeon to the Hospital.

No. I.

Introductory.[a]

The surgery of the eye and its appendages, Gentlemen, has within the last decade undergone a development so rapid, and its literature has at the present day become so deeply involved between speculations unfounded on physiological basis, and proceedings which have not received the sanction of practical experience, that it is necessary for me before entering on my subject to explain what I mean by ophthalmic surgery, and what it is that I propose to offer to you in my course of lectures. I hope it will not be supposed that I undervalue the results which have been achieved by the labour of those ophthalmic surgeons and physicists whose names have been inscribed with honour in the records of modern surgery. On the contrary, I do not hesitate to say that ophthalmic surgery has, within recent years, far outstepped other specialities of our profession, and that the resources of eye surgeons have been enriched in that time by the addition of means which will live to all time as standard procedures of the art. Such contributions to the working materials of ophthalmic surgeons are, compared with the flood of pseudo-scientific material which forms the great bulk of recent ophthalmic literature, as the grain of wheat to the bushel of chaff; and if I were to attempt a recapitulation of even the most valuable of the suggestions or proposals which have been made, I should present you with a *melange* which would be unintelligible to most of you, and useless to all. With the remembrance before me that I am here to afford you information respecting the everyday treatment of the injuries and diseases of the eye which you will be called upon to take the responsibility of in your future practice, I shall endeavour to avoid wandering into the transcendentalisms of the speciality which would require my attention if I were addressing an assembly of ophthalmic surgeons. I must therefore omit notice of many suggestions which have not yet assumed the dignity of accepted practices and procedures, and are therefore unsuited to your position as general surgeons. Many of those suggestions which have received the approval of surgeons who apply themselves to the exclusive study of ophthalmic surgery are quite unfitted for the rough and ready purposes to which the ordinary run of surgeons would require to apply them, and are much too abstruse for you either to comprehend now or to make use of hereafter. Few of you can expect to possess either the special education to follow out the intricacies of ophthalmology—the *tactus eruditus* to effect its difficult manipulations—the confidence to deal with so delicate an organ as the eye, or the inclination to devote to its study the time and labour which is essential to proficiency. For all these reasons I shall aim at supplying you with such information as will enable you to give an accurate diagnosis and prognosis of eye disease, to render you independent of the aid of the oculist in your treatment of such cases as you will usually meet with, to understand and perform the most essential operations, and to add to your professional income by the practice of this amongst other special branches of your profession.

Analogy between Ophthalmic and General Surgery.

The surgery of the eye, while it differs in important respects which I am about to point out, resembles the surgery of other regions in all its fundamental characters. This fact is a necessary consequence of the physiological identity of its constituent structures with those which enter into the construction of the system generally, and though they are apparently distinct, are in reality only varieties or modifications of the same tissues which exist elsewhere. To you who have to treat eye disease on the general surgical principles which you have been taught, it is of the greatest importance that this fact should be kept in view. From it you will learn that the treatment which is adapted to diseases in other parts of the body is applicable (with obvious reservations) to the eye. When, then, a case of eye disease is presented to you, you will certainly treat it best by applying to it the same procedures as you know to be suitable to affections of analogous structures in other parts of the body, modified by the consideration of the local characteristics, and by the activity of treatment which the danger arising from hesitation imposes upon you.

The conjunctiva being simply a reflection of the surrounding skin altered into the condition of a mucous membrane, just as the skin of the cheek is changed when it becomes the lining membrane of the mouth, is subject to the many cuticular diseases. It participates in such eruptive diseases as small-pox and measles, and in herpetic and aphthous affections similar to those to which the mucous membranes of the mouth and lips are subject. Its inflammations are in great measure identical with those of mucous membranes elsewhere—catarrhal discharge, great swelling of the membrane, and the same purulent excretion as is common to the mucous membranes of the nose and bronchi. A catarrhal ophthalmia is nothing more than a coryza of the conjunctiva, purulent ophthalmia is only a blennorrhœa, and diphtheritic ophthalmia a croupal inflammation of the same structure. In the same way the sclerotic or fibrous coat, partaking of the same characters as in tendons, joints, and elsewhere, suffers from gouty and rheumatic diseases.

The iris or muscular diaphragm is the subject of paralysis, as are other muscles, and its investing membrane being analogous to a serous membrane is liable to exudations of lymph and adhesions identical with those occurring in pleuritis and pericarditis. The retina or nervous expansion is similarly liable to the sympathetic and functional disturbances as occur in the other organs. It is the subject of hyperæsthesia, anæsthesia, neuritis, and atrophic softening, and of various obscure diseases and symptoms reflected from other organs.

In the eye we have exactly the same conditions of inflammation, exudation of lymph becoming organised and forming adhesions, or suppurating and being eliminated from the system as foreign matter; and all more or less amenable to the same course of treatment as when they occur in other organs. In point of fact, I repeat, the animal structures are in the eye modified as regards their uses, but still they are the same structures here as elsewhere, subject to the same diseases, and to be combated (with certain limitations) with the same remedial measures. Every general principle which you will learn to apply to the treatment of local diseases elsewhere, will, with restrictions, be found proper to the eye, and must be borne in mind as closely in their application to ophthalmic surgery as in other forms of disease.

---

[a] The substance of this lecture has been already published, but having been re-written it is here re-produced, in order to complete the series, of which it is intended to be the first.

Qualities special to the Eye. But it is to be borne in mind that the eye possesses characteristics which make lesions which would be of the smallest import elsewhere of vital importance here, and which cause an inflammatory process which might be allowed (without much consideration) to persist for weeks in other parts of the animal economy to inflict in a few hours an irreparable injury.

These two qualities are transparency of the media, and that peculiar form of nervous sensibility to light which reposed in the organ. These two characteristics are most vulnerable to all forms of disease; and it is they which make eye surgery a specialty, and which you must bear anxiously in mind in your application of the principles of surgery which I have just impressed upon you.

A little pustule or circumscribed ulcer, a temporary purulent or a passing rheumatic inflammation, may be hardly worth treating elsewhere; but a similar pustule or an ulcer of the cornea, an exudation of lymph from the iris, or an inflammation of the retina, demand special and peculiar treatment, for if they were permitted to go on, as they might do in another position, they would in the eye, while resolution was proceeding, imperil or destroy the transparency of the humours, close up the natural channels for the admission of light, or interfere with the sensibility of the retina. For this reason your treatment of eye affections must, speaking generally, be prompt while it is cautious, and vigorous while it must be judicious; and while you must be careful not to lose time by inefficient measures, you must guard against the mistake too frequently committed of overdoing your treatment, and thereby vitiating your results.

You can only draw a line where it becomes necessary that violent measures shall be resorted to by making yourselves thoroughly efficient in diagnosis, for, in my experience, it is quite as common a mistake to overwhelm the patient with heroic treatment as it is to allow mischief to occur by waiting for the resolution of the disease. You may do quite as much harm by subjecting, as I have often seen done, a puny scrofulous child or chlorotic girl to violent purgation, mercurialisation or depletion for some little pustule of the cornea, as by leaving the pustule to become an ulcer and eat its way through the cornea, deterred from treatment by the fear of doing too much.

Transactions of Societies.

MEDICAL SOCIETY OF LONDON.

JANUARY 29TH, 1872.

DR. ANDREW CLARKE, F.R.C.P., President in the Chair.

SOME CAUTIONS TO BE OBSERVED IN THE USE OF CALOMEL VAPOUR BATHS.

MR. HENRY LEE, who made the above communication, was the first to introduce calomel baths to the notice of the Profession, and before doing so had laboured to find out the cause of failure of the cinnebar and grey oxide of mercury. The cinnebar was decomposed by heat, and gave off sulphurous acid, which irritated the lungs; the grey oxide is decomposed, and absorbing oxygen becomes the bin-oxide, and acts more powerfully. These remedies acted sometimes with small effect, sometimes with great effect. Calomel, when used with water, as he recommended, was, he thought, perfect; the skin was acted upon, and the lungs were not irritated. The caution given to use water with the bath had been neglected in some quarters. During the fumigation of calomel, hydrochloric acid is given off, which is very irritating to the lungs, but no bad results follow it if water is used as well. In the fumigation of calomel dry, without the presence of water, as in fumigation from a tea-pot, hydrochloric acid gets into the lungs and causes much harm.

CASE I.—A young woman, in good health, and well nourished, was suffering from a syphilitic ulcer of the throat. Twenty grains of calomel were volatilised in a tea-pot, and inhaled; the skin became cold and livid, the lips blue, and the pulse small. On a *post-mortem*, for the woman died, the internal organs were healthy, but the lungs were emphysematous, and there was effusion into them. The symptoms appeared suddenly, and the fumigation no doubt caused the death; if a little vapour of water had been present no harm would have happened.

CASE II.—A man inhaled gr. xxx. of calomel from a teapot for four nights, for the cure of a hoarseness which had lasted two years, and which had resisted a great variety of treatment. The hoarseness was cured without salivation, and the man has suffered ever since from a cough, and pain in the chest. The lungs are not diseased, and no tubercle is present. In America the bath is used a great deal, but they make a sweating bath of it, which is an error, as the patient is debilitated, and the calomel washed off.

The PRESIDENT asked Mr. Lee if he had met with any untoward results after his treatment with the bath. What recommendation did he give to those about to use the bath?

MR. LEE had not seen bad results, except from the pre-existing disease—old cases of mercurialisation, or disease of the bones. He does not salivate, but gets a slight tenderness of the gums. He uses an apparatus of tin, with a tray for the calomel, and a gutter for water, a spirit lamp to burn an ounce of spirit, calomel ʒss. A stool, a chair, and a cloak. The calomel is sublimed and deposited on the skin. A little of the vapour is to be inhaled from time to time; the patient is to sleep in the cloak. In four or five nights the gums are affected. In the case of one patient two successive baths produced tender gums. Substances likely to induce diarrhœa are to be avoided.

THE SCIENCE AND ART OF HEALING WOUNDS.

DR. RICHARDSON introduced this subject by observing that no greater evidence of division of opinion existed in the Profession than on the subject of treating wounded surfaces. He sketched the different methods at present adopted in the treatment of wounds, and the anomalies presented in this practice; dwelling first on the treatment of simple, and afterward on complicated wounds. On approaching the question of revision of this subject, the author held—1st. That it was necessary to exclude all extrinsic or imaginary attempts at cure, and secondly to avoid trusting blindly to what was called the "*vis medicatrix naturæ*," for Nature always pursues her own course, without respect to ease or pain, life or death. After this Dr. Richardson proceeded to illustrate from clinical observation the results of healing in extreme cases by the first intention, and then he put the inquiry—Why? If in one case of the extreme kind named there could be cure by the first intention, there should not be such cure in the majority of cases? Why, in short, should success by this method of cure be the exception instead of the rule? Two sets of causes stood in the way, one set remediable, the other irremediable. The remediable obstacles to recovery by the first intention are—want of care in bringing divided surfaces into perfect apposition; the too free use of water in dressing; the too prolonged exposure of wounds to the air; too much manipulation of the surface of the wound; the leaving of long ligatures within the wound; the imperfect closure of wounds from the air; the too hasty removal of dressings; and, lastly, and most important of all, error of judgment on the part of the dresser in respect to the question whether there be, in the case to be treated, sufficient continuity of surface to warrant the attempt to heal by the first intention? The irremediable causes preventing healing by the first intention are—nervous lesions influencing the vascular supply of the injured part; the accidental introduction into the wound of decomposing or other foreign matter; or the generation of organic poisoning product within the body. These causes lie apart from the science and art of dressing wounds, and may be left for a special and future discussion. For the promotion of healing by the first intention, the author contended that the dressing employed should have four distinct qualities; it should be colloidal, elastic, impermeable to air, and styptic. He had himself introduced a fluid possessing these properties, under the name of "styptic colloid," and it answered well, but he had no prejudice in respect to it specially, the principle on which it was constructed being conceded. Healing by the second intention formed the second part of Dr. Richardson's communication. Here, again the rules named in relation to healing by the first intention were considered, and it was maintained that the same colloidal dressing was as effective in curing by the secondary as by the primary process, the difference of application being that the whole of the exposed surface was to be treated with the colloidal fluid. After giving a series of cases of rapid healing by the second intention, cases, in some of which bone had been exposed, and even a joint laid open, and after touching briefly on the addition of iodine to colloidal solution in some particular cases, the author placed before the Society a summary of his arguments in a series of short propositions, and concluded by insisting that Medical men lived to cure all they can, and to try to cure everything until they succeed, through whatever tribulation they may pass in the labour. But if they could become unanimous in respect to the current progress of Medical science and art; if in this simple matter of treating wounds, for instance, they could be of one mind, they would strengthen their bases of operation, clear up as they went on, and would go on more collectedly, noiselessly, and powerfully towards new and certain conquest.

The **President** thanked Dr. Richardson for his paper, saying that for " interest, importance, and literary excellence it was inferior to none of the many that he had read before the Society."

In the discussion which followed,—

Mr. W. Adams said that he considered himself under great obligations to Dr. Richardson for attempting to lay down definite and fixed rules for the management of wounds. He had followed out his plan of treatment in many cases with good results. He amputated the foot of a young man, sawing through the bone; recovery took place in fourteen days. A breast removed by incision healed by the first intention. How far it was applicable to large amputations remains to be seen.

Mr. Bryant said that the most important point in the treatment of wounds was to determine whether adhesion by first or second intention was to be looked for. In principle, surgeons agree, although their practice may be a little different. In a given case, one surgeon might attempt to get primary adhesion, which to another appeared hopeless. Often in a breast the edges of a wound unite, but bleeding, or a serous exudation takes place, undermining the wound and causing suppuration. Deep effusion and suppuration often take place in amputations, although the edges of the wound have adhered. Often, shutting up a wound completely was dangerous. Torsion of arteries was most remarkable in producing healing by the first intention. Pressure, and adaptation of surfaces was most important.

Mr. Spencer Watson, Mr. de Meric, Mr. Weeden Cooke, and Mr. Coles also joined in the discussion.

EPIDEMIOLOGICAL SOCIETY.

January 10th, 1872.

Robert Lawson, Esq., President, in the Chair.

A communication was read from Dr. Jas. Christie, physician to H.H. the Sultan of Zanzibar,

ON "KIDINGA PEPO,"

a peculiar form of exanthematous disease and was epidemic in Zanzibar, east coast of Africa, from July 1870 till January 1871. This fever sprung up after the complete disappearance of cholera, and was recognised by the old inhabitants as identical with one which appeared as an epidemic on the East Coast of Africa about forty-eighty ears ago, it was quite unknown to the natives of India, from Bombay and Scinde, resident in Zanzibar, but the Arabs from Hydramant, on the Gulf of Arabia, were familiar with it. The name "Kidinga Pepo" means cramp-like pains, produced through the agency of an evil spirit. This disease resembles in its most important symptoms "Dengue," or scarlatina rheumatica. The patient is seized very suddenly with pain and stiffness of the muscles, especially those of the palms of the hands and soles of the feet; fever followed, varying greatly in intensity, the skin became hot and dry, the tongue red and spotted, but generally clean, the face of a bright scarlet colour, this colouration was marked in every case, and usually accompanied by a puffy swelling so as to imitate erysipelas of the face, it was characteristic of the disease. There also occurred swelling and pain of the smaller articulations, besides much pain in the shoulders, back, &c. These symptoms were accompanied by very obstinate constipation. This first period of forty-eight hours was followed by a very complete remission of from two to three days; the fever returned on the fourth day always with lessened intensity; on the fifth day an exanthematous eruption neither resembling that of measles, rubeola, or scarlet fever, but more like that of erysipelas, appeared and spread over the whole body in forty-eight hours, then occurred swelling of the lymphatic glands of the head and face, and especially of the occipital glands, redness and even tumefaction and rawness of the mucous membranes of the nose, mouth, and in severe cases, of the throat. During this time the stiffness of the muscles and pain of the articulation continued, and on the seventh or eighth day there was desquamation of the cuticle and the acute stage terminated. The author considers that this disease differs from "Dengue" in several particulars, the swellings of the lymphatic glands did not occur until the third stage of fever, the eruption was invariable in form and as described, unlike that of dengue, which presents many varieties, the implication of the mucous membrane of the mouth and throat and the articular pains were to a greater or less extent invariably present, except when there had been previously attacks of malarious fever, sunstroke, &c., the symptoms and course of the disease were remarkably invariable and characteristic. The sequelæ of "Kidinga Pepo" were much more severe than those of "dengue" the muscular pains may continue for months, and Dr. Christie himself who was the first European attacked, suffered severely for two months afterwards. These chronic pains affected especially the shoulder, wrist, and ankle-joints, and in addition to them there was chronic tendency of the superficial lymphatics. The disease appeared to be communicable, the members of a household being usually attacked one after the other; "the Europeans suffered much more acutely than the natives, and very few escaped an attack; in no case did the disease recur in an acute form, and there were no fatal cases either among children or adults." The disease was treated during the first day with purgatives and five-grain doses of quinine; on the remission of the fever, iodide of potassium in four grain doses was administered with the most marked effect on the articular pains. Dr. Christie says, "I know of no medicine more entitled to the name of a specific than the iodide, its effect in subduing the disease being more marked than those of quinine in the treatment of malarious fever."

During the discussion which followed the reading of the paper it was suggested that the word *Dengue* might possibly be a corruption of *Kidinga*.

◆

EDINBURGH MEDICO-CHIRURGICAL SOCIETY.

January 17th, 1872.

Dr. Fergus, Glasgow, read an interesting communication on

THE SANITARY ASPECT OF THE SEWAGE QUESTION, WITH REMARKS ON A LITTLE-NOTICED CAUSE OF TYPHOID FEVER AND OTHER ZYMOTICS.

The more he studied the subject the more convinced had he become that the present system of water carriage is a mistake. Its enclosed rivers and streams are in many places nothing better than cesspools, and in proof of this the condition of the Thames, the Tyne, and the Clyde was adduced. On the banks of the last-named river there are plenty of chemical works, but it was only after the rapid introduction of water-closets into Glasgow that salmon ceased to pass up the river. In Glasgow alone there are 32,500 water-closets discharging into the Clyde, and it is but a fair inference to deduce that these are the chief causes of the pollution of the river. In the author's opinion the condition of rivers loaded with organic refuse in a state of putrefaction is not injurious to health. It is only when decomposing excreta are placed in narrow passages with a limited supply of air and water, as in our cesspools and sewers, that they become so. These sewers are connected with our houses by water-closets more or less out of repair and imperfect, and with fixed basins, some of them having merely pipes passing from the water-closets to the sewers. Trapping and ventilating sewers is injurious, inasmuch that if we trap in one place we leave more to escape in another. Ventilation is not easy, and is very costly. Mr. Bazalgette estimates the ventilation of the sewers of London at £460,000, with an annual expense of £201,480 for fuel, exclusive of labour. Trapping and ventilating merely dilutes the poison, and lowers the health of the surrounding inhabitants by contaminating the air. Sewage gas, always forming, is generally lighter and hotter than air, and being frequently in a state of tension, will ascend and escape at the highest point. After stating how ineffectual any present system of trapping was in preventing the escape of sewage gas into houses, and instancing various epidemic diseases originating from sewage gas, the author stated that fifteen years ago he first detected perforated soil pipes. These perforations were generally on the upper surface of the pipe, and the pipe usually affected was the cross one leading from the closet to the main descending soil-pipe, and if there were an arch in the pipe the upper surface of the arch would be perforated. The author exhibited several specimens of perforated pipes, showing clearly that the destructive action was from within. Considering the results of chemical analysis, as well as the increased rapidity with which this action takes place in pipes not ventilated, he believed himself justified in coming to the conclusion that the perforation was due to the action of sewage gas. He found on inquiry that the same state of thing exists in every water-closet town. Lead being usually employed as the material for soil-pipes, it becomes important to inquire how long a good lead soil-pipe will hold out. In unventilated pipes the duration might be stated to be about twelve years, when the pipe is carried up to the top of the house, and open to the external air, the maximum duration is from twenty to thirty years. The practical conclusion upon which the author insisted was that in any house, however well built, when cases of typhoid fever, diphtheria, &c., occur, the pipes should be thoroughly inspected, especially their upper surface, and the whole of the soil-pipe uncovered. Sewer gas may also prove injurious by passing up the waste pipe of the cistern, and becoming absorbed by the water. The plan of sewage irrigation Dr. Fergus considered would not in the least improve the sanitary condition of water-closet towns. The most perfect specimen of this system was at Croydon, but experience shows that the excreta are not passed first on to the land, and that the excreta must take much longer than from four to six hours, the theoretical time allowed to pass from the closet through pipes and over meadows. Again, if sewage is pumped, in all probability the liquid will be pumped up and the gas left, as confirmed by the results of drainage works in twenty-five towns in England. The result at which he had arrived was, that all excreta should be submitted to chemical or other action, by which they shall be rendered non-putrescible. After noticing the various plans which had been suggested for meeting the whole case, it appeared to him that the apparatus devised by Mr. Hoey supplying all the comforts and conveniences of the water-closet, gets quit at once of all the nuisance and dangers of that system, and the expense of altering a water-closet to suit this apparatus would be 13s. The author has one fitted up in his own house, which works admirably.

SURGICAL SOCIETY OF IRELAND.

January 19th, 1872.

J. H. Wharton, F.R.C.S., President of the Royal College of Surgeons, in the chair.

The Society met at half-past eight o'clock p.m.

EXCISION OF THE KNEE-JOINT.

Mr. E. Hamilton said: The specimen I have the honour of laying before the Society is one of disease of the knee-joint, presenting some peculiar features. A boy of about nineteen years of age, presented himself for admission to Stevens' Hospital, suffering from extensive disease of the left knee-joint. The knee was bent and enlarged, and he suffered most excruciating pain. I don't think I have ever seen a case in which the pain was so intense and acute. He lay in bed with the knee bent, and supported by the opposite leg, and the slightest movement caused him the greatest agony. He suffered a good deal of constitutional disturbance—hectic, night sweats, diarrhœa, rapid pulse; and he presented all the appearances of marked constitutional disturbance produced by the condition of the joint. The history that he gave was that for a year before, he was in the habit of being exposed to the air and damp, taking a great deal of exercise, and laying on the damp ground after a day of more than usual fatigue. Things went on for some months thus, when he was attacked with a severe pain in the joint, and was disqualified from pursuing his ordinary business. He suffered from shocks at night, and the least contact of the foot with the ground caused great pain. He applied for admission to the Rathdown Workhouse, where he was treated for the ordinary affection, and he was then sent up to Stevens' Hospital by the surgeon of Rathdown Infirmary. It was clearly a case of disease of the joint in which the cartilages had become engaged; and I believe we may accept it as a tolerably general rule, that when we have these sudden attacks of extensive pain, we are justified in saying that the cartilage has become affected, although cases are on record where there is no pain with great affection of the cartilage. We drew the conclusion here that the cartilages had been attacked. The joint was carefully examined by myself and my colleagues. I may mention that there was no appearance of ulceration about the joint—no breach of the skin—no sinus. The question came to be considered as to what was best to be done—as to whether the patient should be subjected to excision or to amputation; my own predilections are rather against the excision. I have tried it two or three times, and without success; but taking into account the age of the patient, and the condition of the joint, we thought there was not probably much disease, and that if we could remove the painful condition of the joint without any other mutilation of the patient, we might place him in a fair way to recovery. The operation of excision was undertaken on last Saturday week. I shall not trouble you with the details. I may say, however, that the incision was a plain semilunar one. I did that advisedly, because I am satisfied that the less we cut in this operation the greater are our chances of success. By this incision the parts were exposed with sufficient freedom: the ends of the bones were sawn off; but on examining the femur, it was found necessary to remove a slice, as the surface of the femur was rather soft. Hæmorrhage was stopped by torsion, the wound sponged out with chloralum, the ordinary solution diluted with two parts of water; and, though it is not fair to state the value of a remedy from a single case, so far as I could see it appeared to act as a powerful styptic; and what I have seen will induce me to give it further trial. The parts were brought together by the carbolic catgut, in order that we should have no trouble afterwards, and to leave the wound as long as we could undisturbed. There was also left on each side of the wound a portion which was not closed, and the main portion of it was closed very accurately with a great number of stitches, and in the side openings was a bit of carbolised lint for the escaping of discharges. On making the incision, I should mention that we found a small abscess reaching up into the muscles of the thigh. It discharged a little matter, but it gave us no further trouble; we emptied it, and allowed it to remain. There is one point about which I wish to say a word, and that is about leaving the patella. Whether that is culpable or not I do not know; but I was very much in doubt as to what I ought to do, and I shall be glad to know the opinion of men of experience in the Society upon this point. My own opinion is against the removal of the patella, if it could be avoided, for it leaves a nasty bag close to the skin, and often collects a quantity of matter that tends to disturbance. I think the less we cut and remove of this the better for the patient. If the patella could be left in its bed it would retain its vitality, and be of good service in establishing the solidity of the bone. I have here the portions that have been removed, which I think present a peculiarity. As a rule we find the ulceration is more apt to extend from the synovial membrane, which in this case is perfectly healthy. There is no appearance of the vascular fringes, described by Aston Key, and others, but the membrane can be peeled off the bone without any trouble. Here we had inflammation of the bone, and commencing ulceration. It is a remarkable fact that the cartilage lying thus in the joint did not produce suppuration; yet there was a very small amount of matter in the joint, and no external abscess whatever. Of course, it is premature to speak of the result of the case, but up to the present it has done well. His pulse has fallen, there are no night sweats, and the limb has been several times changed; he has no pain, but he appears to be of a weakly constitution. The case is interesting from the disease spreading from the bone to the cartilage, rather than from the synovial membrane to the cartilage.

Mr. Stapleton said he had seen four or five cases of this kind. He had seen inflammation not only of the femur, but of the tibia. The cartilages could be peeled off. There was no ulceration of them, and there was nothing wrong with the synovial membrane, showing, as often occurs in hip disease, that the mischief begins in the bone and not in the joint. In one case of amputation he had to go higher up because the bone was diseased a long way up. The tibia was the same. He believed there were startings in Mr. Hamilton's case.

Mr. Hamilton.—Yes.

Mr. Stapleton said he saw a case in which the late Mr. O'Reilly amputated, and both bones were found destroyed. This man suffered torture from starting of the limb and spasm. Whether these cases were the best, catching them at the proper time, for excision of the joint he could not say. He would like to know where the abscess was.

Mr. Hamilton.—Up among the extensor tendons.

Mr. F. T. Porter asked whether Mr. Hamilton had any statistics as to the advisability of leaving the patella.

Mr. Fleming said that the case had been so very accurately and truthfully reported by Mr. Hamilton that it carried with it much practical value. He (Mr. Fleming) had witnessed the progress of the case, and the performance of the operation. With respect to the condition of the joint itself, and in particular that condition which had been specially noted, regarding the loose attachment of the cartilages, he thought they had many opportunities of witnessing that in the several diseases of the joints, not alone of the knee, but of the hip and other joints that are usually the seat of disease. He had repeatedly seen it in the knee; and even in the case of the patella, which was not removed, he was sure Mr. Hamilton would bear him out in saying that by merely passing a spatula under the cartilage, he was able absolutely to shoot it up from its bed, without the slightest attachment, the only thing apparent being remarkable softness and vascularity of the bone. The other point that was worthy of attention was the non-removal of the patella. It would be in the memory of many that in the earlier cases of excision of joints the patella was left. He recollected having met Professor Syme in Edinburgh, and being not present at the operation, but in the preparatory stages of a case of a gentleman whose loss must ever be regretted—Dr. Mackenzie, of London, who had not been long appointed to the Infirmary. In two cases of his which he (Mr. Fleming) saw, the patella was left, and he thought the general impression at the time was that the leaving of the patella was not followed by the results that were expected. No doubt it interfered more or less with the perfect healing of the limb. Mr. Syme was not in favour of leaving the patella, but it was a matter worthy of consideration, particularly when they recollected the provision that must be made in the lower part of the femur for the accurate adaptation of the patella itself, and whether or not a sufficient provision was made under the circumstances in the condition of the limb. He had seen Sir W. Fergusson obliged to remove two sections of the femur, in a case where the disease was found to extend higher than was expected. He recollected having remarked to him that it was particularly unfortunate that such a course should be called for in that case, inasmuch as the section was beyond the epiphysary line, and they knew what sometimes happened in such circumstances, and the subsequent deformity that existed.

The President expressed a hope that Mr. Hamilton would allude to the loose condition of the cartilages on the condyles. He believed that this loose condition never could arise from disease commencing in the cartilage itself, but always arose from disease beginning in the bone.

Mr. Richardson said that if there was one surgical question more than another of which he was certain, it was that complete destruction of articular cartilage may take place without the patient having ever suffered from spasm of the limb. He had over and over again observed this, particularly in children, and had seen it verified by dissection. Indeed, if his memory did not fail him, Mr. Redfern had given, in his work on "Articular Cartilage," cases in which the cartilage had disappeared from joint-bones without causing symptoms referable to it.

Mr. Hamilton, in reply, said, with regard to Mr. Stapleton's observation, he believed that cartilage could undergo ulceration on either surface, on the synovial, and on the osseous surface; and he looked upon this case as one of ulceration commencing on the osseous surface, ulceration being so closely allied to mortification arising from imperfect nutrition. With respect to Mr. Porter's question, he might say that the statistics given in Holmes', Vol. V. were rather unfavourable to leaving the patella, as those cases took some days longer to come to a favourable conclusion. But he could not subscribe to Mr. Holmes' statement that it is a matter beyond all doubt that it is perfectly useless to think of saving the patella. He found the statement in Erichsen, with whom he was more inclined to join, that they ought not to remove the patella, unless it was absolutely necessary, and he thought that was more in accordance with conservative surgery. He had already alluded to the fact that ulceration of cartilage might occur without pain or constitutional disturbance, or spasm.

PROCEEDINGS OF THE DUBLIN OBSTETRICAL SOCIETY.

A meeting of this Society was held in the College of Physicians, Kildare street, on the 20th of January, 1872.

Dr. Sipthorpe in the Chair.

The statistical statement of the practice of the Rotundo Lying-in Hospital was read by Dr. Johnston, Master of the Hospital. An abstract of the paper appeared in our issue of Jan. 31.

Dr. Churchill considered that Dr. Johnston had proved that the theory set forward that the patient is more likely to contract disease in an hospital after confinement than if delivered at her own home, has little or no foundation.

Dr. Atthill said—It was impossible to over-estimate the value of the details which Dr. Johnston has drawn up with so much care. He thought the author had clearly proved that the mere fact of a large number of puerperal women being delivered and congregated together in one building does not necessarily generate disease. Stress had been laid by some writers, on the fact that the *relative* mortality of the Rotundo Hospital has largely increased. This is capable of easy explanation, if it be borne in mind that the Lying-in Hospital was formerly extensively resorted to by the wives of the artisan class, who now, from various causes, do not seek admission, and are now delivered at home. But the destitute, who are peculiarly prone to the disease, the wretched victims of seduction, and the bad cases—sent in because they are bad—are as numerous as ever, and it is among these that the mortality, as shown by Dr. Johnston's report, mainly arises. The mortality of some other hospitals has been favourably, although most unfairly, contrasted with the Rotundo, for those hospitals do not admit any except married woman; the "bad cases," and the wretchedly poor, are as numerous as ever, while the number of respectable women admitted has fallen off.

Dr. McClintock thought that the report was a most important step towards the settling of this vexed question of hospitalism. There are two sources of mortality in the Rotundo Hospital. One large source of mortality arises from the number of unmarried women who go into the hospital, and there is no class of persons among whom the proportion of deaths is so great in childbed. The other is the immense number of primiparous cases. Out of 1,161 cases admitted, there were 553 primiparæ, nearly half the entire number, and there is a much greater danger to life amongst this class of cases than any others, as every man of experience well knows. Dr. Duncan has shown that the number of primiparous cases is about 23 per cent. of all cases in the population at large, but we have double that number in the Lying-in Hospital during the year of the present report. It is apparent that the relative number of primiparous cases has been increasing of recent years in the Rotundo. During Dr. Collins' Mastership they were 30½ per cent. of the entire; during my own seven years' Mastership they were 37 per cent.; and in this present report, drawn up by Dr. Johnston, they are about 47 per cent.

Dr. Denham thought it would be a satisfactory thing to know the amount of mortality outside as well as inside the hospital. As to the mortality among primiparæ, that is a thing in which we are all concerned. With regard to the number of married women, we have no certain data to show that a woman admitted into the hospital is married, and it is probably only at the hour of death that it comes to the knowledge of the Master or the Assistant that she is not married; and I am sure that a number of women have come in thus, and have had a very narrow escape of their lives, have gone out leaving the impression that they were married women.

Dr. Fitzpatrick said—There was one portion of Dr. Johnston's paper with regard to forceps cases to which he would wish to refer. Twenty years ago he was taught not to use the forceps except in extreme cases, but now the forceps are frequently used. He thought there is one thing that should be impressed on the present generation of students, that is, that the use of the forceps may be pushed too far, just as the crochet was used in former times improperly.

Dr. William Cuppaidge, M.B., Castlerea, related a case of

PREMATURE QUADRUPLE BIRTH.

The occurrence of quadruple birth in the human subject is of extreme rarity. The records of the Rotundo Lying-in Hospital, though covering a period of over one hundred years, and including nearly two hundred thousand deliveries, only show one example of a pregnancy of four children. A patient was attended by a midwife; she was 19 years of age; it was her first pregnancy, so that she was just about entering the six month of uterogestation. I returned at 5 p.m., and just as I got into her room a small female fœtus of about the fifth month was expelled, head foremost. The woman's size not having diminished, I examined and found another bag of membranes pressing through the os. Supposing that this second fœtus would be expelled as easily as the first, I went away. There was no return of pains, and the patient slept during the night. In the morning I gave a dose of ergot, which was soon followed by the expulsion of a *second* fœtus, male, with the feet foremost. On examining the patient now, I found the membranes of another fœtus; these I at once ruptured, whereupon a *third* child, female, was expelled, the breech presenting. After its birth, I again instituted a careful vaginal examination, and was greatly surprised at discovering another bag of membranes, which I at once ruptured, when the fourth fœtus—a male, head presenting—was delivered. The first two children, I may here remark, were born alive, and cried but did not long survive. The third and fourth children showed no signs of life at birth.

Dr. McClintock said he had looked over the registry of the Lying-in Hospital, and found—as the author of the paper states—that there was only one year since 1757, in which a quadruple birth had occurred. It took place on the 30th October, 1788, in Dr. Clarke's Mastership. The name of the woman was Mrs. Hood, she was 30 years of age, and it was recorded in the register that she was an Irish woman (laughter). The children in this case were born alive and baptised, but subsequently died, though the day of their death was not mentioned. The woman herself left the hospital at the end of fourteen days. Dr. McClintock proceeded to say that there was a preparation in the Museum of the Lying-in Hospital of five children simultaneously conceived. The entry, which appeared in the Museum catalogue for that year (1839) was as follows:—"Five children simultaneously conceived; three separate ovas; one single with its placenta; the others twins, each furnished with a common placenta; three months pregnant; miscarried in the summer, 1839. This woman was several times subsequently in the hospital, on one of which occasions, he (Dr. McClintock) saw her. She was a stout sanguine woman with fiery red hair, and the wife of a tailor. She alluded with no small pride, to having once being pregnant of five children!

MEETING OF MEDICAL OFFICERS OF HEALTH OF LONDON.

February 8th.

Dr. Druitt in the Chair.

Mr. Acton read a paper on—

THE REPORT OF THE ROYAL COMMISSION ON THE CONTAGIOUS DISEASES ACTS.

There was not a very large attendance, the notice having been very short.

Mr. Acton observed that in the Report of the Royal Commission he read that the appearance of the women was very much improved by the operation of the Acts. The cases of syphilis were much less severe than formerly. Women, in former days, at Aldershot, had to be hunted out of the drains, &c.; and women, when first examined, had been very bad, and must have been diseased some time. One woman, in days gone by, had often infected a great number of men. One patient had connection with nearly 90 soldiers when suffering grievously from mucous tubercles. The state of syphilis near Westminster was very bad in 1871. The places existing without "protection" are much worse than those where there is protection. A prostitute does not die of these venereal diseases; and, as these women are frequently barren, they often live in comparative comfort if they marry. The women marry in most instances, and get away from their trade. A woman now gets the man to marry her more easily in protected districts. The frequency of venereal disease among civil hospitals is very great. Continental armies are much less infected than ours. Sir J. Paget says that many diseases of the internal organs are syphilitic, and he adds, it would be difficult to exaggerate the evil done by syphilis. Hewitt said he found it one of the most frightful of all diseases. Dr. Farr says that 651 children under five died of the disease in one year. Syphilis, now-a-days, rarely produces falling in of the nose, as it used to do when mercury was abused, and when *twelve men* used to be so *salivated* in one ward at St. Bartholomew's Hospital for a month at a time. The discovery of iodide of potassium was a great improvement, and the cause why there is not so much evil now-a-days occasioned by syphilis. In 1865, 108 per 1,000 of the naval troops; in 1869, only 59 per 1,000 were found to be infected. In the Army, Balfour, in 28 stations, in 1865, found 120 per 1,000 infected, and, in 1870, 54 in 1,000. Public solicitation is less. The *Contagious Diseases Acts* have done good in reclaiming the women: the discipline of the Acts was severe, and many women were reformed. *Opposition to the Acts*—Most of the inflammatory statements made at the public meetings were false. *Objections*—The women get higher wages, and this tempts to prostitution; the Acts are opposed to the principle of Constitutional Law. Those who advocate the Acts lay themselves open to the imputation of immorality, but they tend to do good, instead of harm. Rev. Mr. Maguire, of Cork, C.P., says "the mortality of the troops is not worse since the Acts came in." Rev. Mr. Puckle says the same. Mrs. Butler had admitted that a woman might be kept in hospital by force when sick in her evidence before the Commission. If libertines and married men go to the protected district they might easily catch gonorrhœa. Mrs. Butler had said she would rather that her three sons should die than live in a protected country: he did not agree with this. Eighty-seven medical men in London had lately said that women would not object to compulsory surgical examinations. In conclusion, Mr. Acton said that the periodical examinations ought on no account to be discontinued. Numerous innocent wives suffered, and so did children. Vaccination was compulsory.

Dr. C. R. Drysdale was as anxious as Mr. Acton to see the ravages of syphilis put an end to; but thought that the idea of making a law for the Army against the women of the country was unjust; and that it would be better to allow our home troops to marry like policemen, and engage other troops for foreign service merely for the campaign, if this were feasible. As to applying such Acts to the whole population, the example of Paris showed how absurd it was to expect much from such police laws. There were calculated to be 50,000 cases of contagious disease in Paris annually, and 40,000 prostitutes, of whom only 4,000 were examined. As to virtuous wives being infected by their husbands, of course, the common-sense remedy for such a breach of trust would be to get divorce *a vinculo* at once to any wife who desired it in such cases, accompanied by ample damages. Instead of the Contagious Diseases Acts, he recommended ample hospital accommodation, as in Paris, of a voluntary kind; and if funds were not obtainable by private effort, was prepared to urge on the Government that all persons suffering from any kind of infectious or contagious disease should obtain relief in some Government Hospitals, such as those under Hardy's Act. He hoped this compromise he suggested might be accepted by both parties, and this wrangling might cease.

Mr. Holland began by some very severe denunciations of the Anti-Contagious Diseases party (for which he was called to order by the chairman). He contended that it was just as fair to tax people for the Contagious Diseases Acts as for any other purpose. The Acts had much reduced disease in the Army, and had made the women more moral. It was absurd to say they were unjust to women.

Dr. Moet said that the citizens of India were under civil government, just like the people of this country, and the Acts now were carried out at Calcutta, &c. He found the men greatly diseased in India thirty-two years ago, when it was the custom to examine them very carefully. At Aden there was no syphilis, on account of the inspection of the women. He was in favour, then, of the Contagious Diseases Acts from his own experience of their operation, and did not agree with Dr. Drysdale.

Dr. Septimus Gibbon said that when he was Inspector of Vaccination at one time he found that three per cent. of the children disabled from vaccination were syphilitic. Dr. Drysdale has raised a difficulty about the soldiers. A soldier costs £200, and should be kept in health. Dr. Drysdale, he said, should compare Englishmen with Englishmen, not English with French as he had done. *Remedies*—Dr. Drysdale says he would give the wife a remedy by divorce; but that was because he was an advocate for women's suffrage, and would be a mockery for the women. We ought to put down open prostitution. Voluntary State hospitals would not act. The young women would not enter these hospitals. It was only the older ones that would enter them. There should be a memorial to the Home Secretary in favour of the Acts.

Mr. Milton gives his strongest testimony in favour of the Acts. The dissolution of manners in Paris, described by Dr, Drysdale, was not caused by these Acts. If it were possible to get rid of syphilis, it would be a good thing to put us all under martial law. Syphilis among women of the lower classes, is a grave affair, and 60 per cent. of cases of infantile syphilis died under any treatment. Scrofula has nothing to do with syphilis. The conduct of woman in speaking of this Act was shameful. The Act should be extended to the whole population.

Mr. Webster.—Notwithstanding all the arguments used by Mr. Acton, he disapproved of the Acts. In foreign countries such Acts did not succeed well. Syphilis is very common in Paris. Mr. Carlier (Oct. No. *Ann. d'Hygiene*) says that from 1860 to 1862 the entries into the Lourcine and Midi were 14,711; and from 1867 to 1869 there entered 16,147. The *filles clandestines* are much increased in numbers. The *insoumises* in Paris are most frequently diseased. Go to Naples, Madrid, Rome, &c.; you find immorality is much increased. Naples has increased immorality by such Acts, and not diminished the disease. This question must be decided by such facts. A new kind of industry is common in Naples, &c.—ruffiani or procurers are very common. The law is very partial as applied only to women in France, &c. In the Hospital at Naples the perfunctory nature of the examinations was noticeable. It would be far more important if the State would rather turn its attention to preventing delicate people from breeding delicate children, than to putting women under laws like this.

Dr. Deacon said that the Contagious Diseases Acts do not put women in any special disability. Dr. Vintras thinks there are far more cases of syphilis in London than in Paris. The trade at Hamburg is simply tolerated, not licensed; very few women found themselves against the Acts. Divorce of husband, as proposed by Dr. Drysdale, would be more opposed to our ideas than the Contagious Diseases Acts. Voluntary hospitals would not do; twenty-five per cent. of the women would not enter them. There has been a Lock Hospital at Winchester which was empty. The Contagious Diseases Acts are not new; 50 to 80,000 prostitutes in London are considered to subsist by the trade.

Dr. Druitt said the fewer men that go with prostitutes the less syphilis would there be; and if it were thought good to examine women, it would be equally fair to take up prostitutes when seen exercising their trade, and put them in prison; thus, prostitution might be repressed. He once made a tour of Hyde Park, and found many poor girls in great misery bivouacking among the trees. This was an example of failure of police supervision.

Mr. Acton said he was much pleased with the progress the question had made since he read a paper on it last year, and if the ladies and clergy would second their efforts, he hoped the Acts might be extended to the whole population. Examination of soldiers, he said, ought to be resumed throughout the service in a more decent manner, and then it would be efficient.

A letter was read from Dr. Letheby approving of the Acts, but objecting to papers which were going round for signature at present, because such declarations, just like that on alcohol, tended to intimidate.

◆

SCOTLAND.

EDINBURGH.

The sum of £5,000 has been bequeathed to the University of Edinburgh by the late Mr. Robert Cox, of which £2,000 are to be devoted to general purposes, and £3,000 to the completion of the College buildings. Mr. Cox specifies in particular his desire that the dome over the great gateway should be completed.

The University Authorities have instituted an inquiry as to the riotous proceedings at the recent Rectorial Installation, which has resulted in one student being rusticated, and several fined. Some of the ringleaders were found not to be students, but strangers, who had obtained admission to the hall under pretence of being students.

Dr. James Dunsmure, jun., has been appointed Extra-Physician to the Royal Hospital for Sick Children, in room of the late Dr. John Millar.

St. Andrew's University.—It will be recollected that Mr. Ruskin was elected Lord Rector of the University in opposition to Lord Lytton, and that objections were taken as to the validity of his election on account of his holding a chair at Oxford. The opinion of eminent counsel is, that Mr. Ruskin is ineligible on this account, and also that Lord Lytton must be held as having been elected to the office of Lord Rector.

◆

Triplets with Dropsy of the Amnion.

Dr. E. S. Ray, in the *Atlanta Medical and Surgical Journal*, reports an interesting case of enormous distension of the uterus. Before confinement a diagnosis could not be made out of the exact condition of things, though the fœtal heart was heard, and there was a dulness over the symphysis pubis. At all other places the fluctuation was very distinct. The suffering of the woman from the distension was so great that it was deemed proper to draw off the fluid by a trochar. But ere this could be done, the woman was delivered of three children and five gallons of water. Two of the children were born dead, and the third died in half-an-hour. Particular notice is drawn to the fact that in this case it was impossible to separate amniotic from peritoneal dropsy. Though most of the gentlemen called in consultation agreed that she was pregnant, they were more certain that she had peritoneal dropsy which tapping alone could relieve.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, FEBRUARY 21, 1872.

THE DEBATE ON THE SANITARY BILL.

It is not often we can afford to spend a Friday night in the Gallery of the House of Commons; the miscellaneous character of the Notice paper; the singular method adopted in reading its contents, the impossibility of gathering the faintest idea of the "*when*" the thing will come on, which you desire to hear, and the more than chance that the thing you don't want to know will be forced upon you in the place of what you do want, render the night's profit or amusement the most problematical thing in the world. We went to learn something about the new Sanitary Law, and the skill with which the Right Honourable gentleman the President of the Local Government Department would introduce it to a House, which from the out-of-Parliament speeches we fondly deemed would be full—not to say—inconveniently crammed. We secured an "orders" paper and found we must dine early, for "the Bill to amend the law relating to public health" stood at the top of the notices of motion. Let us see! Petitions one quarter of an hour; unopposed returns, another quarter; minister-badgerings half-an-hour or so; total one hour, or, granting grace, one hour and a half, say then half-past five! We must be in our quiet corner of the Gallery with our paper and pencil on the sly dotting down the salient ideas, before six. But six mortal hours had we to wait whilst every conceivable, or inconceivable topic was waded through; the House, meanwhile, becoming thinner and thinner. The new Speaker, patient and conspicuous, in a very white wig and a very black gown, falls back in his very large chair, and evidently is overpowered at last. At a few minutes to midnight, Mr. Stansfeld takes his place in the midst of the ministerial bench, Mr. Hibbert on one side, and, further down, Mr. Winterbotham and some other face indistinctly visible; just behind sits Sir Thomas Acland and Dr. Playfair; on the row behind them there was only an occasional occupant, whilst on the fourth row, sat one solitary member, Dr. Brewer. Below the gangway, sat in front, Mr. Torrens, M.P. for Finsbury, and a little knot of honourable gentleman, near the door. On the Opposition side sat Sir C. Adderley, behind him Mr. Powell the new member, and below that Lord Eustace Cecil. The few unmentioned names, who flitted in an out on this occasion, which, we were told, was to eclipse in interest the sensational legislation of the preceding session, added little or nothing to the imposing grandeur of the exciting scene. We were favourably, very favourably impressed with the tone and bearing of the Right Honourable gentleman, who introduced the bill, with an apologetic phrase for the lateness of the hour, and the thinness of the House. He said his bill was but the logical sequence of the legislation last year on the subject of Local Government, which fused the old Poor-law Board, the medical department of the Privy Council, and the general sanitary authority of Government into one body. His bill was a Sanitary Bill and nothing more. It was founded upon the Report of the Sanitary Commission, which however contained a series of 33 resolutions, the first of which declared that the consolidation of the sanitary law might profitably be undertaken consentaneously with the amendment of the law. This was cheered, but the Right Honourable gentleman went on to say he was not justified in undertaking so heavy a task, the bill proposing such an action contained 450 clauses, whereas his bill contained but 80, which, by the Right Honourable baronet opposite, might be supplemented by consolidation clauses, to which he would lend all the aid in his power. He proposed hereafter to establish country Boards, as the local authorities of rural districts for sanitary functions, the conservancy of rivers, and the maintenance of highways. In the meantime, his object was to reconstruct, and add new sanitary powers to, local authorities. Dividing sanitary acts into Urban and Rural, he attributed the failure in administration to something different from mere defect of power: powers were given under existing Acts for cleansing houses, for keeping ambulances, removal of the infected, and the establishment of mortuaries; for ample supply of water, medicine and medical attendance to the poorer classes of the population; but local authorities had not availed themselves of the power. His first object was then to improve the construction of the machinery for carrying properly into effect the powers granted by the Legislature. For this, three requisites were urgent, a central and governmental supervision and inspection, and authorities so constituted that but one sanitary authority should be appointed in one place, and distinct responsibility should be attached to these authorities, and sanitary legislature should drop its permissive character and become compulsory. Urban authorities were Town Councils, or Improvement Commissioners, or Local Boards. The Rural, would be Boards of Guardians; upon these bodies, under strict supervision, would the carrying out of general sanitary functions devolve. Pure air and pure water were the first desiderata. Both wanted in doors—more perhaps than out of doors. Something would be within the power of the authorities to effect under the powers of the Act, a right to enter, to inspect and remedy defects in drainage; a power to test the water supplied, and a power to test for the discovery of adulteration in food. A duty to provide hospitals, and the appliances and medical attendance for the treatment of epidemics, and these powers were to extend to the Rural, as well as to Urban districts. To appoint sanitary officers and to provide drugs, no longer exacting them from the medical attendants as even yet too often obtained. The Government hoped, by these means, to secure statistics of disease and mortality, and by the addition of a measure enforce compulsory registration of births and marriages to secure a bill which would do credit to the House, and prove of lasting benefit to the population of the country.

Sir Charles Adderley expressed great disappointment that the consolidation clauses were omitted; the state of the sanitary legislature of the country was a disgrace to the legislature. Local authorities, when honestly desirous of carrying out the sanitary enactments, knew not which statute to investigate, or by which law to commence proceedings, and no wonder, for the legal profession were unable to advise them. The confusion of the law was the cause of those defects in administration which allowed conditions to continue fatal to the health and strength of the country. The existing statutes, unconsolidated, would so prejudice the new Act as to render it an additional evil rather than a benefit. The 450 clauses, to which the right honourable gentleman referred, were little more than the classification of clauses scattered through the Statute book, with the contradictory enactments harmonised or removed. The apprehension of the President of the Local Government Board, based on the number of the clauses, was ill founded; but although he was disappointed, he would support him zealously in passing his bill. Mr. Johnson and Mr. Powell both suggested a point or two, and Dr. Brewer, who had been zealously taking notes during the delivery of Mr. Stansfeld's speech, rose when the house was just supplied by three or four more members, waiting to give their several notices of motion, and therefore only anxious to go home. He expressed his disappointment with Sir C. Adderley that the long hoped-for consolidation clauses were dropped out of the bill, and hoped the right honourable baronet would not delay the introduction of his measure, with which he expressed his hearty concurrence. The scourge which had been inflicted not only on the metropolis—a scourge, he urged, hardly parallelled in intensity within the last thirty years, and which had spread disease far and wide—had reasonably drawn attention to the sanitary organisation of the metropolis and other great towns. It was impossible to contradict the soundness of the too general conclusion that this organisation had failed. If, observed Dr. Brewer, they could point out the "why," they had taken the first step to the remedy. Local Boards had not, perhaps, understood the directions of the legislature, for whilst in seeming they had generally complied, they had not really carried out the purposes indicated. Take the permissive provision for testing food. He held in his hand last year's return of the appointments of these analysts by the then 39 parishes and unions in the metropolis; 29 had failed to appoint, and, by the remaining 10, the real purpose had been frustrated from misunderstanding the object of the legislature. The directions sent in 1855 to Local Boards by the Board of Health to appoint officers of health had been apparently complied with, but, in reality, neither in letter, nor in intention. The Board of Health directed that one or more parishes should elect an officer of health; 2ndly, that he should devote his whole time to his special duties. The Board then went on to express the intention and object it had in view, namely, that the officer should acquaint himself with the special sanitary defects of his district, and report the results, so that the central authority might obtain the benefit of his local knowledge, to the intent that the Department of State, responsible for the sanitary condition and the introduction of sanitary requirements to the legislature, might be informed of the results of the experience and observation of the district sanitary officers. But local bodies disobeyed the letter of the directions. Desirous, perhaps, of the entire control of the officers they employed, each parish elected one or two sanitary medical officers, and, seeing that the expense would be formidable, did not remove them from private practice. The failing to group parishes so as to form convenient districts, and obtain local knowledge sufficiently extended to make the facts acquired available for the information of the central authority, the medical officer of health soon became a sort of nuisance removal officer, or head clerk and constable to his own inspectors. Waggon loads of returns, and often repetitions, extracts from the Registrar General's reports, and tables were reproduced and laid before Local Boards, never to be utilised, often not even to be read. The failure of the central authority in requiring suitable returns has suffered thousands to be expended, not perhaps without object, but for other than the contemplated purposes; and it would be in vain for the President of the Local Government Board to find officials if the head were to be, as heretofore, severed from the mass. He, Dr. Brewer, should give his support to the measure of his right honourable friend, but, whilst regretting some of the omissions apparent in the bill, he equally regretted the late hour and the state of the House in which so important a measure was introduced. The House, by this time composed of about as many members as there are fingers on one's hand, broke up wearily, Lord Eustace Cecil, brother of the Marquis of Salisbury, giving notice that he should put on the notice paper a clause to extend the duties of the analyst to the testing of drugs. One thing seemed indisputable, that the outcry about the interest felt on social reform is a delusion or a sham.

◆

SIR W. W. GULL ON CLINICAL MEDICINE.

Sir W. Gull's address at the Clinical Society having found its way even into non-professional papers perhaps demands at our hands the attention which some of our correspondents ask for it, and yet as the author expressly stated at the commencement he had had no time to prepare, he may not perhaps himself attach great importance to it. He startled some of his hearers at the outset, and ourselves amongst them, by calling the theologic aspects of the world antagonistic to the scientific. Sir William asserted that theology regards the world as decaying, but science as progressing; but we venture to say that few theologians will admit the proposition thus laid down.

Proceeding, then, to speculate on the nature of disease, the President of the Clinical Society remarked that in one sense there is no such thing. Though disease is not definable he called it that course of nature in a living thing which is not according to its health.

Disease is not an entity, said the President, though to the ignorant it seems so, and the old theologians thought that an evil spirit entered a man. Hence the term seizure remains although there is no such thing.

Some people, he said, are always ailing, without having disease. They are born to suffer; unstable health is the law of their life, and all the drugs in the Pharmacopœia cannot alter it. Thus the work of the medical man includes all the disturbing influences that act on the human organisation. But we do not know in detail where morbific causes begin, and he instanced scarlatina in which, though some would say it begins in the blood, it seemed to him very doubtful whether the blood was directly affected in that or any other fever—remarking, many organs well supplied with blood show no change, as voluntary muscles. He looked to comparative anatomy and pathology to tell us something, and adopting apparently in its coarsest form the so called Darwinian hypothesis, caused quite a little sensation by saying, "What is the use of tonsils? Were I to make a man I do not think I would put any tonsils in him," and referred to other instances of what he considered relics of a former stage of development.

The President dwelt next on the importance of perfecting vital diagnosis which should warn us against attempting the impossible upon those born with a feeble vital capacity, as those delicate women who have no more strength than a canary, and on which the chemistry of tonics may be tried in vain. "It is only trying to put a quart measure into a pint."

The importance of perfecting physical diagnosis was admitted, but even in this department Sir William seemed to be doubtful, and said he had more than once laid aside his thermometer because it contradicted his clinical experience.

He then made a few remarks on insanity, prompted by his having been consulted in reference to recent criminal cases, and lastly turned to therapeutics, on which he said:—

The other aspects of medicine might afford sufficiently pleasant contemplations, but *finis coronat opus*—care, and where possible medication, in order to cure. We are often twitted with being, as I have before said, merely passive attendants upon and worshippers of Nature. As Goethe satirically says, "Man durchstudirt die gross', und klein welt um es am ende gehen lassen wie's Gott gefallt." This, however, I repudiate. We believe that God's will is that we should be wise and active, and when we say, and I am sure our Profession is not behind any in devoutly saying, "Thy will be done," it is not that we may sit down, like fatalist Moslems, and let the supposed inevitable pass over us; but ours is an active interpretation of the prayer, that we may learn the Divine will in order to obey it, convinced that the Divine will is the exact contrary of ignorance. There is, no doubt, a time to each when he must bear the lot in patience and submissively, but, as students and practitioners of medicine, our interpretation of the Divine prayer is in an active sense, and should excite us to every exertion. The will of God, as expressed in the purposes of the human intellect, is apt to be too lightly passed over, but he who has but a faint conception of that purpose will not be open to Goethe's remark of letting events pass on without any effort to control them. It is only they who are weak in faith and intellect who exclaim, "The world (time) is out of joint. Oh, wretched spite that ever I was born to set it right!"—for this is our true sphere of work. Whilst we more clearly discern the operation of those forces which bring health out of disease, we are not contented to be spectators only. Efforts of nature are regarded with watchfulness and doubt, and often must we agree with Professor Haughton, who, when told that the evacuations of cholera were due to an effort of Nature to cure the disease, said: "I will tell you what Nature wants; she wants to put the man in his coffin. And that is what she succeeds in doing for the most part." In fact, the expression "effort of nature" is little else than a vague metaphysical conception, a mere *imago* of the true and practical *idea* of the recuperative forces which are at work in the organism, and which collectively we name the *vis medicatrix naturæ*—that centripetal tendency which restores the disturbed relations. Were we able to make a due analysis of this tendency in us, it would indicate a true science of therapeutics. It would show that in the subject of typhus or typhoid, or other fever, there were, together with the more obvious fever facts, others correlated to them, by which health is for the most part restored. In other words, that under the conditions of disease there lie physiological processes, which not only restore the normal equilibrium, but which leave a permanent resistance to any similar disturbance. The causes of this immunity are as much facts for our study as are those which we more commonly call the disease. For example, in small-pox, to the indifferent observer the whole disease is embraced in the description of its symptoms and the eruption; but there is a most important obverse to these in those prominent physiological changes by which the subject of them is likely to obtain a permanent indifference to the variolous process. I desire more expressly to say that, in the class of fevers, what we term the disease is but the attendant disturbance of an underlying process, which being completed, its accidents subside. We owe a very practical application of these views to Dr. Stokes, of Dublin. In some excellent papers on fever, he long ago pointed out that the various local affections in fever must be looked upon as part of the fever itself, and not as separated or separable conditions. I well remember the time when the irritation of the brain in fever was regarded as inflammation of the meninges, to be treated with mercurial inunction; when irritation of the bowels and the fetid evacuations, were to be corrected by giving the grey powder; the obstruction of the air-passages to be medicated by blisters and expectorants. So, when I had to teach medicine, I impressed as far as I could upon the students of my class the importance in therapeutics of minding these local affections as Nelson minded the signal given him to retire from action; whilst, on the other hand, we maintain to the best of our power the strength of the patient.

In therapeutics we have no kinship with those who believe that diseases are only sets of symptoms to be combated by drugs. The symptoms of a disease may indeed give but doubtful indications for treatment. The worst diseases have but few and not prominent symptoms, and even when the symptoms are characteristic they are not the disease, and frequently the most numerous symptoms occur without any disease at all. It may be all very well for the charlatan to make them the whole object of his efforts, but to the better informed the chief fact is the condition which underlies and produces them. In therapeutics the greater often depends upon the less. It has been said that Wellington overcame his great antagonist by attending to the shoes of his soldiers. This may have been so, for often we see great purposes frustrated by neglect of trifles; a man brought through his fever and dying of bed-sore; a broken spine in process of repair, whilst death comes on from the careless passing of a catheter. With the gold-headed cane and the horsehair wig passed, we may hope, the days of pompous inanity; and we may further hope that nothing will be thought unworthy the attention of the physician which can contribute to the saving of a life.

For the surgeons, as I have hinted, a new prospect is opening. Should advancing knowledge show that we have parts or organs of doubtful use, and especially if these equivocal parts are liable to disease,— what a land of promise for operations!

But I must forbear. I am sure we have a hopeful future before us, though it may not be in such a direction, and it is my duty and my privilege to invite you to enter upon it with industrious hands and true hearts.

Notes on Current Topics.

How Editors may serve the Filthy Quacks.

THE fight we have carried on against the tribe of filthy quacks has been approved almost unanimously by respectable public journals. In one or two instances the plea has been put in that, contracts for advertising had been unwittingly made, and also that the business columns were outside editorial supervision. But these scoundrels may be met by some means or other, and in America, where they are so numerous as here, a spirited editor has done something in the way of giving a warning. We take from a contemporary of the Far West, the following account:—

The best thing of the kind that our eyes have ever beheld, is presented in the two following articles, which appear nearly side by side in the *Pacific Observer*, a religious paper published in San Francisco. We commend the example to other papers which publish the advertisements of Darrin, Doherty, Gibbon, Cohen, Madame Exodius, and so forth. If the editors should say what they think, all the speculators on human credulity and human life would be complimented in terms similar to those meted out to the "Rev. William H. Norton:"

TO THE SUFFERING.—The Rev. William H. Norton, while residing in Brazil as a missionary, discovered in that land of medicines a remedy for consumption, scrofula, sore throat, coughs, colds, asthma, and nervous weakness. This remedy has cured myself after all other medicines had failed. Wishing to benefit the suffering, I will send the receipt for preparing this remedy to all who desire, free of charge. Please send an envelope with your name and address on it. Address, Rev. William H. Norton, 676 Broadway, New York City.

CAUTION.—We caution our readers against the advertisement of one Rev. William H. Norton, found in the advertising colums of this paper. The advertisement is one of the vilest swindles ever perpetrated upon the community. In the first place, there is no such man as the Rev. William H. Norton. The name is assumed by a consummate knave and villain, to steal money from the afflicted. You are ready to enquire if a prescription, free of charge, is robbery or stealing? There is the secret. In that pretended benevolence is compounded the quintessence of knavery and villainy. You write to him, enclosing stamped envelope, and he will send you a prescription in such names as nobody ever heard of but himself, which he manufactures for the occasion; you will take that to the druggist to have it filled, and find that he has no such articles. You will ransack town and city in vain to get your benevolent prescription filled; and in despair you will write the Rev. villain that you cannot find such articles as he mentions. Now, he has you in the mouth of his net. He will write to you immediately, that if you will remit him five or ten dollars, he will send you the medicine. Remit him the money, and by the return mail or express will come a package of some worthless powder; most usually rotten wood, made bitter with a little gentian or quassia, or a bottle of mean whisky, made bitter with the same articles. You are sold, swindled, outraged, but to attempt to catch the Rev. rogue would be like the Irishman's flea—"'taint there." You may write to responsible parties in New York, stating your grievances, but they will tell you there is no such man to be found. The name is assumed, and his habitation, if such he has, is in the deepest den of the Five Points. We say to readers, beware! Thousands are swindled out of their hard earnings by such villains. How such advertisements get into newspapers is a mystery.

Liebreich on Chloral Hydrate.

IN the *Gazette Hebdomadaire* for Dec., is an article by Professor Liebreich, in which the conditions of the use of chloral are laid down more definitely than they have heretofore been. All cases of insomnia without fever form the basis of its application. For the relief of severe pain, it cannot be depended on, without the addition of opiates. The counter-indications pointed out by Liebreich are as follows:—

1. Extended destructive affections of the mucous surfaces of the primæ viæ. Here the remedy, if used, must be much diluted with mucilage; or it may be thrown in the rectum.

2. Arthritic conditions are unfavourable, unless the blood be first rendered alkaline.

3. In typhus, if given, it should be in small doses.

4. In affections of the circulating apparatus, particularly valvular and other serious troubles of the heart, small doses should be used.

5. Hysteria is often a counter-indication. Here it often increases and fixes the condition of excitement. An inexplicable phenomenon, says Liebreich.

6. Icterus has been regarded as presenting a counter-indication; but this is doubtful.

The author goes on to say that it should never be given in substance, nor in solution stronger than 20 parts to 100.

It may be mixed in beer, wine, beef tea, and mucilage. He prefers syrup of orange peel. The so-called syrups of chloral hydrate are solutions in glycerine with sugar. Thin gruel may be employed as a vehicle for an enema. In certain convulsive attacks it may be applied hypodermically. The cigarettes which have been proposed are inadmissible. The best dose for adults is from 30 to 45 grains. Habitual use does not require increase of dose. "Long continued use does not impair the general health. I know persons who have taken it almost daily since its introduction in the same dose and with the same success."

Dr. Lostorpher's Views.

DR. C. R. DRYSDALE writes, respecting the translation of this in our last issue, to say that there is great scepticism among the Medical men of Vienna as to the supposed discovery by Dr. Lostorpher of syphilitic corpuscles in the blood by means of the microscope. Dr. Kraus, the able editor of the *Alg. Wien. M. Zeit.* and others say that Drs. Stricker, Hebra, and others, have been deceived and done most unwisely by forming their opinion so rapidly. Skoda also seems to have been very precipitate.

Royal Free Hospital.

THE differences between the Medical Staff and the Weekly Board are not yet at an end; and we deeply regret to hear that one member of the staff refuses to be guided by the opinions of the majority of his colleagues. Such conduct as this will always put Medical men under the power of the industrial and less educated classes, who take so much advantage of our want of unanimity. Points like this should be taken up by all Medical journals; and a Court of Appeal in questions of this kind would soon bring offenders to their senses. We hear that the museum of the hospital is in the most deplorable condition. The Royal Free Hospital is such an excellent institution, and its staff is so distinguished, that we hope soon to hear that intestine disagreements have terminated to their satisfaction.

The Scheme for a Conjoint Examining Board in Ireland.

THE scheme as agreed to by the conference of delegates of licensing bodies has been presented to those bodies, and has been under the consideration of their councils within the last week. The Report has not been made public, but we are aware that the sketch of the two most important of its clauses which we gave last week is correct. These are the provisions which will probably determine either the acquiescence or dissent of the licensing bodies, and it will depend on their adoption or modification to decide whether an Irish Conjoint Board can be formed or not.

The first of these clauses is substantially "that no licensing body shall be empowered to grant any qualification until the candidate shall pass the Conjoint Board; that the student shall only pay a nominal fee for cost of examining, and it shall then be open to him, after he has passed, to go to any Body he likes and claim their qualifications without further test, paying for it any fee the Body chooses to demand. Inasmuch as he will not be permitted to register until he can show some of the qualifications recognised by the Medical Act, he will be obliged, if he wishes to register, to go to some licensing body.

We have already said that we regard this proposed arrangement as very objectionable, and we now give our reasons *seriatim* for the sake of distinction:—

1. Because it is undesirable to afford facilities or inducements for the admission of the profession to a class of practitioners who, having obtained the *status* conferred by the conjoint examination at a nominal cost, would be enabled to enter into practice without seeking any further qualification whatsoever.
2. Because, inasmuch as (the conjoint examination having been passed) nothing would remain to be conferred by the licensing body, except the right to register and hold a public appointment, an obvious inducement would be afforded to the candidate to seek the cheapest legal title which carries with it such privileges, to meet which contingency no provision is suggested for the equalising of the fees payable by all licensing bodies.
3. Because it may be certainly anticipated that before long the conjoint examination would be declared to be the essential qualification for registration, or for the holding of public offices, in which contingency the licensing corporations would necessarily become extinct.

The second leading clause is one which gives to graduates in arts of a university a special favour, enabling them to present themselves for the last of these conjoint examinations without going through the two previous ones to which all other candidates are subject. We object to this clause for the following reasons:—

1. Because it is contrary to that uniformity which is the essential principle of a conjoint examination, that the students of any licensing body should be assumed without evi- evidence to be in possession of superior professional attainments.
2. Because it is inequitable and imprudent to afford special favour to any licensing body by subjecting its students to a lower examinational test than is considered necessary to secure the proper standard of proficiency in others.
3. Because the recognition of such distinctions between one licensing body and another introduces into the system that doubt as to the sufficiency of the teaching arrangements in schools, which it is the object of the conjoint examination to get rid of.

Lord Houghton on Medical Peerages.

It is something to find a highly cultivated nobleman like Lord Houghton endorse our demand for Peerages for the profession. Although in his article in the *Fortnightly* he does not expect much from the influence of individuals, he admits that there is "no reason why men of great ability, information, or experience should not from time to time be added to the House of Lords, though not in such numbers as to prejudice its constitution. At the present moment, when, owing to the direction of the public mind aided by the pressure of certain distressing events, sanitary subjects are likely to be prominent, the accession of one or two eminent medical practitioners, or men versed in the application of physical science, would assuredly not be unwelcome."

Hunter's Day.

There was a break this year in the Annual Orations delivered at the Royal College of Surgeons of England in honour of John Hunter, of whose museum the college is the guardian.

Hunter's Day, however, was not unremembered; for Professor Erasmus Wilson brought to a close on that anniversary the course of lectures "On Dermatology," now in course of publication in the MEDICAL PRESS AND CIRCULAR, and in so doing, took occasion to pay a tribute to the memory of the founder of the greatest museum in the world. This he did in the following terms:—

"I cannot take my leave without being reminded that this is the anniversary of our great and distinguished master JOHN HUNTER; a man to whose comprehensive mind every work of the Creator was interesting and important, in whose sight nothing was too small for observation, and nothing created in vain, whether the humblest plant or animal, or the highest example of organisation.

In the field of pathology, in all its departments, his zeal and faith were equally energetic and pure; whether he were investigating what may be termed the "physiology of pathology," as in his grand labours "On the Blood," "On Inflammation," "On Syphilis," or whether he were illustrating morbid changes in the integument. He has left behind him in the splendid museum, which will for ever be a chaplet to his fame, many valuable specimens of dermatological interest; and if his spirit be with us and round about us this day—as I doubt not it is—I am fain to hope that he will not look disapprovingly on our present occupation; I believe it to be impossible that he could do so; no whole would seem perfect to him without the perfection of its parts; for the soul of HUNTER was essentially all-absorbing and universal."

Mr. Robert Patterson, F.R.S., the well-known zoologist, died last week at his residence in Belfast.

The authorities of the Middlesex Hospital have just received a fourth donation of £1,000 from an anonymous friend, who simply gives the initials D. T. S.

The first of the Gulstonian Lectures at the Royal College of Physicians of London, will be delivered on Friday, at 5 P.M. The lecturer is Dr. Hensley, and the subject "On the Mechanism of Respiration, Circulation, and Digestion."

The Belgian *Medical Press* is translating from our columns the communications of Mr. Critchett "On Cataract," into French. A short time since the same journal translated the paper read by Dr. Prosser James "On Ozæna," at the Medical Society of London, from the abstract in our columns. We are glad to see our contemporary keeping *au courant* with English Medical literature. It is to the pen of its able collaborateur, Dr. de Jouet, that these and other translations are due. Other journals have also lately reproduced many articles from our pages. Thus, the *Independent* translated the above-named article on ozæna into Italian, and the article that Dr. Prosser James contributed to the MEDICAL PRESS AND CIRCULAR of the 10th January on "Diseases of the Throat," has been published in German by the *Vien. Med. Zeit.*

THE RELATION OF STIMULANTS TO HEALTH AND MORTALITY.

THE following return, which we commented on in a recent issue of our Journal, was submitted to the Mountmellick Board of Guardians by their clerk, Mr. Goodbody, at their last meeting.

Returns, showing the daily average number of persons relieved in 91 workhouses during the year ended 29th September, 1871; the cost of wine, ale, and spirits used in each of said Unions, with the average cost of same per head on the number relieved; the number of deaths during same period in 84 workhouses, with the proportion of deaths to the numbers relieved :—

UNIONS.		Average daily No. of persons relivd.	Cost of Wine, Beer, and Spirits for the year.			Cost of Stimulants per head on average No. relieved.		No. of Deaths during the year.	Per centage of Deaths to average No. relieved.

(Continued from previous column.)

Class a.—20 Unions in which the cost of stimulants for the year does not exceed 1s. per head on the average number relieved. Mortality, 22½ per cent.

Class b.—30 Unions in which the cost of stimulants for the year exceeds 1s., but does not exceed 5s. per head on the average number relieved. Mortality, 22¾.

Class c.—34 Unions in which the cost of stimulants for the year exceeds 5s. per head. Mortality, 25.

Seven Unions marked (*) have not sent any return of the mortality.

ROBERT GOODBODY,
Clerk of Mountmelick Union.

27th January, 1872.

◆

THE SMALL-POX IN DUBLIN.

WE are favoured with the following report from Dr. Burnside, Medical Officer to the South Union Hospital :—

55 South Richmond street,
February 17, 1872.

In reply to your inquiries concerning the progress of the small-pox epidemic, I beg to inform you that the hospital in connection with the South Dublin Union was opened for the admission of small-pox patients in November last. From the middle of that month to the present date the total number of admissions have been 444 ; 279 of these have been discharged well, and 86 have died—not a fifth of the total. I consider this a small proportion when it is remembered that the majority of cases are in an advanced stage of the disease on admission, and also that in many instances the symptoms are much aggravated by the abuse of stimulants. This arises from the very popular delusion that strong drink is not only a remedy for every malady under the sun, but that it also acts as a preventive to disease, as not only the patients arrive drunk but also their attendants. A case came under Dr. Brady's observation the other day of a girl only ten years of age, to whom her fond mother had administered a whole noggin of whiskey made into punch, and beat the poor child because she objected to swallow the whole of the potion. The natural consequence was, that the child was quite tipsy when Dr. Brady went to examine her in the ward.

Out of the total number of admissions, 77 on careful examination had *no vaccine marks;* 26 out of this number have been discharged well, and several are now on generous diet, and will soon, I trust, be fit for drafting to the Convalescent Hospital previous to discharge.

Out of the total number of admissions we have had no less than 81 children under ten years of age, and nearly a third of the number under five years.

The number of admissions weekly on an average since the 17th of December have been 35.

The last fortnight or so the disease has certainly assumed a milder character; but I cannot agree with some that have stated that throughout the epidemic has been of a mild type, as I have treated as virulent cases of confluent small-pox since I have been attending the South Dublin Union Hospital as ever I saw in the East Indies during my ten years' sojourn there.

The purpuric form that some make a distinct variety of the disease I do not acknowledge as such. I look on it as simply a complication. The cases I have observed it best marked in were adults that had led intemperate lives, whose constitutions had consequently become impaired. These, as a rule, rapidly succumb to any serious illness; and also in pregnant women. In the latter death has been preceded by severe flooding. All the purpuric cases ended fatally.

I think it nonsense pretending to lay down any specific mode of treatment. My maxims have been very simple, viz., to assist Nature as much as possible, to carefully watch for symptoms, and treat them when they arise. The first I endeavour to carry out by attending to the secretions, relieving the bowels at least once in the twenty-four hours. This, if the throat symptoms are urgent, I do by the ordinary purgative enema of tepid water, soap, and salt. The discharges are, as a rule, large in quantity and most offensive, and followed by much relief to the patient. Sleeplessness is often a serious symptom, and I use anodynes freely, a few hours' sleep often placing the patient fairly on the other side of the balance. In the desquamative stage, I maintain the strength carefully by frequent administrations of strong beef-tea. I have had as much as thirty-five pounds of solid beef boiled down for hospital use in the twenty-four hours.

The throat symptoms, which many have laid such stress on, are almost the usual accompaniment of every case, only they are more urgent in cases that promise to be severe, and also in those of the lymphatic temperament. I relieve them externally by hot turpentine fomentations, and internally by a gargle composed of solution of chlorinated soda, tinct. of catechu, or rhatany and water. They disappear as if by magic when the disease becomes well developed.

I need not say that the appliances that have been recommended from time to time to prevent pitting are rather numerous. The application that I have used from the commencement has, at least, the advantage of simplicity, and I have turned out very few much marked; simply sometimes a mixture of castor and olive oil well smeared over the whole body two or three times a day. This relieves the itching, and softens the crusts. I also have bags made to tie up the hands in.

My sheet-anchor all through has been to sustain the strength, as the drain on the system during the stage of desquamation is very great, and it surely stands to reason the sooner the drain is supplied the sooner convalescence is established; and I think I am also safe in saying that the abscesses that are often a sequelæ, are lessened in number in many very bad cases. Indeed, I have had none.

Wine and whiskey I have used only in cases actually requiring stimulation. I pin my faith a great deal more in strong beef-tea, milk, and eggs, and on frequent observation and good nursing. I give porter during convalescence.

The sanitary arrangements have been carefully attended to, at the least three to four feet between each bed. The sheds are thoroughly ventilated. There is a convalescent ward for both males and females; open pans filled with chloride of lime scattered through each ward; the bedclothes frequently sprinkled with a dilute solution of chlorinated soda; the discharges dusted with M'Dougal's disinfecting powder, and at once removed from the ward. I use warm baths in convalescence.

None of the attendants—and they are thirty-six in number—have been attacked as yet with variola. I don't make re-vaccination compulsory, but merely told them that any that wished or felt at all nervous about the disease could be re-vaccinated. Seven of them presented themselves for re-vaccination. The soiled clothes are steeped for hours in a solution of carbolic acid before being boiled and washed. I have seen the disease distinctly modified after re-vaccination; but then, again, I have seen a mild type of the disease in cases that have never been vaccinated. I make this statement from observation, not wishing for a moment that any one should think that I am not a firm believer in the great benefit conferred by vaccination and in re-vaccination when a person is of a nervous temperament.

The discoloration of the skin, I observe, disappears much sooner in fair-skinned people, although it is more apparent at first; but sallow people do not bleach near so quickly,—I suppose it must be because the skin is thick as a rule, and the sebaceous follicles more numerous.

The secondary fever, as a rule, has been very slight.

I am, Sir, yours truly,
G. S. **Burnside**,
Medical Officer to the South Dublin
Small-pox Hospital.

Literature.

PRACTICAL LESSONS ON THE NATURE AND TREATMENT OF THE CONTAGIOUS DISEASES. (*a*)

This is a most instructive work, and reflects great credit on Dr. Morgan for the immense labour he has bestowed in bringing it out, and the originality which has prompted him to make investigations in untrodden paths. In the preface the author says truly that the recent debates on the Contagious Diseases Acts have given an immense impulse to the study of venereal contagions. He thinks that "it is not much to be wondered at that enthusiasts, among the non-professional ranks, should violently oppose a measure which would be so evidently beneficial to the community at large, as they could not practically observe the various cruel penalties inflicted by the disease, not only on the guilty, but on the innocent, and on their offspring." He does not say, however, that some professional people, among others Mr. H. Lee, &c., share the

---

(*a*) "Practical Lessons on the Nature and Treatment of the Contagious Diseases." An account of the Primary Syphilitic Lesion, and of its Communicability, with an Appendix on the recent report of the Royal Commission on the Contagious Diseases Acts, and its application to the Voluntary Hospital System. By John Morgan, M.D., F.R.C.S., Surgeon to Mercer's Hospital, and to the Westmoreland Lock Hospital, Dublin, &c., with 67 Illustrations, plain and coloured. London: Baillière, Tindall, and Cox, 20 King William street. 1872. Pp. [illegible] convictions of the non-professionals as to the inutility and inadvisability of such acts. Dr. Morgan's object in many of the pages of this interesting work is to prove that another "futile source of contagion is exposed (by him) which has hitherto not been noticed at all." Hence, "a more rigid enforcement of an act which has been proved already so beneficial wherever exercised, should be in my judgment (he says) invariably observed."

The vexed question of the existence of one poison, or of an infecting and non-infecting form, he refers to at some length, and brings some *post obit* evidences of Mr. Wallace's of inoculations on healthy and untainted subjects to bear on this subject, which, though practised so long ago as nearly half a century, confirm what has been just now proved of the inoculation of the soft or non-infecting type as an offshoot from the infecting. "An interesting paper by Dr. Bradley (says Dr. Morgan), at the meeting of the British Medical Association this year, experimentally decides the question." We are glad to hear Dr. Morgan say, what we have long thought that, "a specialist in contagious diseases is indeed an impossibility, every hospital and dispensary surgeon, and every general practitioner, has but too ample opportunities of personal observations." Before going further, we would ask Dr. Morgan whether the title of the work on *Contagious Diseases* is not rather misleading? Scabies, variola, and ringworm, &c., are contagious diseases, and, on the Continent, his title would be liable to misinterpretation. Could he not, in a subsequent edition give another sub-title, such as *Venereal Diseases?* We throw this out as a suggestion to the author.

In page 2, the author shows his penetration when he speaks of the strong analogies between syphilis and those diseases of the lower animals produced by the presence of low vegetable forms in the blood. The recent revelations in the Viennese Medical Society seem to show the accuracy of these observations. "Amongst these (says our author) the history of the silk-worm disease is full of interest, and the diseased phenomena are most remarkable. Careful investigators sought out and expended much time and labour in investigating the extraordinary phases of this affection; it was found that a number of corpuscles, not more than 1-6,000th of an inch in length, permeated the blood of the silk-worm, and swarmed in every tissue of the creature's body. This product has been aptly termed the *Panhistophyton*. Not only did these appear and flourish in the caterpillar, but they also were transmitted to the egg itself, and thus the grub emerged into life tainted with the morbific and propagating germs, which speedily led to its destruction. The disease itself was eminently contagious, and, as is well known, caused immense destruction. The syphilitic poison is similar in its effects; it is propagative by contact; it is, though not necessarily destructive, yet most injurious to the individual, and it is again capable of being propagated as an hereditary taint, and the offspring afterwards manifests all the signs of its reception." It is really most ingenious of our author to suggest the discovery just made at Vienna, and we give him much credit for his sagacity. He says truly that microscopists are now able to define objects 1-40,000th of an inch in diameter.

In page 24, Dr. Morgan says, "while in hospital practice, the soft, simple, or non-contaminating sore is most frequent, in private practice the indurated or specific sore is rather in the ascendant." Dr. Fournier, of Paris, ascribes this to the fact that the poorer classes of men consort with older prostitutes, who are no longer subject to indurated sores, whilst richer men have to do with young women, who, of course, are more likely to labour under the initial lesions of syphilis. In page 35, he says he shall show in pages 60, 64, &c., that a purulent discharge on an infected female can produce, when inoculated, undoubted soft or chancroid sores, capable of auto-inoculation and *re*-auto-inoculation in syphilised subjects, and that this discharge conducts itself as other secondary products are known to do—it is not unreasonable to conclude that did such a secretion communicate a gonorrhœa, it might, as derived from a syphilitic source, be capable of conveying constitutional infection, or, it may be of producing but the local effects of the soft sore. And further down he asks: "Is there a syphilitic gonorrhœa, without the ascertainable existence of a chancre inside the urethral canal? or does the existence of a gonorrhœa followed by constitutional signs entail the necessary occurrence of a urethral sore, the essential existence of which is so often fallen back on in dubious cases, as explanatory of the infection of the system." Hammond (United States), he says, has made experiments which show,—1. That the virus of an infecting chancre deposited in the urethra will originate inflammation and discharge, without the necessary formation of a sore, unless there be an accidental abrasion. 2. That there is a syphilitic gonorrhœa capable of evolving constitutional signs. 3. That the virus of soft chancre, when deposited in a like manner, gives rise to an inflammation and discharge, without the necessary formation of a local sore; that this is capable of giving a similar discharge to another person, but is not followed by specific signs. 4. That discharges may originate from stimulating food, venery, acrid applications, injuries, ascarides, and instruments, without specific character." In page 39, he gives an experiment of Wallace, of Dublin, in 1835, which is very curious. "M. Connor, Feb. 21, suffering from a primary sore on the prepuce, and an ulcerated bubo. Passed lint dipped in the matter of J. Gavan's sore (phagedænic) and in his own matter (chancroid) into his urethra. This was followed by urethral discharge. February 24th.—Much more discharge.

Dr. Morgan says that in females there is a great paucity of hard sore, and remarks that out of the last 1,000 patients treated in the Lock Hospital, Dublin, the number of indurated sores registered had been only twenty. In page 50 he says, "Mr. Egan, from his observations and experiments at the Lock Hospital, Dublin, for five years, from 1843 to 1848 found the indurated sore was also auto-inoculable; so much so, that he states, (p. 29) "It is more expressly in reference to the next class of primary affections, the indurated and excavated ulcer of Mr. Hunter, that inoculation can be truly relied on as supplying a valuable test. Twenty-nine such ulcers fell under my observation, and in all inoculation was performed, and in every instance, with but one exception, the characteristic pustule was the result of the operation. In the process of syphilisation this remark has been so fully verified, that Bœck absolutely selects the discharge from an indurated sore for auto-inoculation or syphilisation." In page 53, he says, "The Committee appointed by Government report that, it is declared in evidence, by twenty-nine experienced witnesses, that sores, both soft and hard, may be followed by any variety of syphilitic eruption." In Germany, Hebra supports the unicist theory; Bœck and Bidenkap advocate the theory of unicity, &c. From all these quotations, it may be seen that Dr. Morgan is himself no dualist. We differ from him; but admit that he has many things to say for his side.

Many pages are devoted by the author to the details of his experiments on auto-inoculation of gonorrhœa in prostitutes, producing ulcers. They are all most worthy of study, and of being repeated by other observers. In page 76, he tells how Mr. Messenger Bradley, of Manchester (British Medical Association, 1871), gave the details of three cases in which he had succeeded in producing an auto-inoculable, freely suppurating, non-infecting soft chancre, by direct inoculation from a true infecting chancre.

Two of these cases occurred in guinea-pigs, the remaining one in a kitten; in each instance he had taken a scraping from the surface of the *unirritated* sore, and produced the mature resultant chancre *within a week* from the date of the inoculation. So that, says our author, page 77, "If we briefly sum up the evidence in favour of the unity of the syphilitic poison Mr. Bradley believed, we must consider it conclusive; it is quite true that the interchange of the lesions takes place very rarely. Thus the great majority of Mr. Bradley's experiments failed" (about

95 per cent). We can hardly think this proves unicity at all. In page 80, Dr. Morgan says that in most cases the incubation period was very short.

Does not Dr. Morgan himself see the flaw in his cases? If the author would only look at Fournier's cases "sur l'incubation," he would see that incubation is *usually* longish when inoculations are made from true syphilis.

In page 100, he says that Dr. Bumstead, of New York, admits that sometimes it is very difficult to inoculate patients from any virus, and Mr. H. Lee writes that "in certain states of the system in syphilitic patients a pustule and sore can be produced by inoculation with great ease." In page 107, he says "experience both at home and abroad has shown that cauterisation of the *indurated* sore does not usually secure against constitutional taint." The exhibition of mercury is wholly uncalled for in chancroid, the cachexia, perhaps induced by mercury injudiciously given, is sometimes the exciting cause of phagedæna. There are some excellent plates of diseases of the various organs, such as vegetations, diseases of the larynx, &c. He gives examples of gummata in the mammary gland, in the heart, &c. In page 217, he gives praise to Mr. Reade, of Belfast, who as long as 34 years ago turned his attention to syphilitic diseases of the brain and nerves. Locomotor ataxia is sometimes syphilitic, and should be treated by large doses of iodide of potassium. Syphilitic hemiplegia he says (page 259), is comparatively rare. Paraplegia is a casual effect of syphilis of the bones. Epilepsy "is commonly easily got rid of," says Ricord, when syphilitic. Perhaps sometimes, but by no means so very frequently.

In adults, the rectum and large intestines suffer from distinct and well-marked ulceration during the late or gummy deposit stage of syphilis. In one case, in a female who died, *post mortem* examination showed that ulceration had extended up the entire rectum fully one-and-a-half inches wide, by eighteen to twenty in length. It had completely cut away the mucous coating. The liver seems the viscus most liable to tertiary syphilitic deposit, says Dr. Morgan. He gives a good plate of a case which died of syphilitic cachexia, and when the liver was examined. In page 243, he relates the case of a man with syphilitic albuminuria, who recovered perfectly under remedies. He does not give any very full account of syphilis in the lungs, kidneys, or other viscera.

With regard to treatment, in page 256, Dr. Morgan says that the Parliamentary Venereal Commission stated that, "No treatment by mercury, whether moderately or freely administered for the purpose, can give exemption from the liability to constitutional disease." These are the best reasons therefore for the *general rule* of not giving mercury for the treatment of the primary ulcer. Our author states that he is with some exceptions to be included in the ranks of the favourers of mercury in infants, in the treatment of parents, and in secondary symptoms. He prefers to rub in twenty grains of ung. hydrag. fort., with a few drops of glycerine added, every second morning alternating from the axilla and sides to the groins and thighs. A Turkish bath to be taken thrice a week, or every day. A suppository of ten grains of mercurial ointment is also praised. This course to be continued some six weeks, and then left off. Dr. Morgan speaks, page 269, rather favourably of Dr. Bœck's plan of syphilisation. "It requires careful and unprejudiced inquiries in these countries." For our own part we must confess that we think that syphilisation is merely expectation and worse than no treatment, and that iodine is the most innocent and useful remedy for the disease.

Mucous patches are to be kept clean and dusted with equal parts of calomel and tannin. Sinapisms and warm baths for rheumatoid pains are recommended. The prognosis of s. iritis is very good. Atropine or belladonna extract locally, with gr. v. of Plummer's pill twice or thrice a day is used in hospital. In private practice, results are not so satisfactory. In weak persons, bark, pot. iod., &c., must be had recourse to. Eruptions may be well treated by Turkish baths; sore-throat with nitrate of silver. Syphilitic testicle in the early period is well treated by mercury, or later on ten grain doses of iodide of potassium. The use of iodide of potassium is recommended in all gummata. Bisulphate of calcium gargle is praised in syphilitic sore-throat. Both mercury and iodine are recommended in laryngitis. Osteocopic pain requires the iodides; nodes, and blisters. In rupia, iodide of potassium and iron should be given. In visceral syphilis, arsenic is useful. Mercury, as a rule, is not desirable in tertiaries.

With regard to inherited syphilis, Dr. Morgan thinks that a spermatozooid may convey infection. He knows well that this has been doubted. We doubt it greatly. A large proportion of syphilitic children die hydrocephalic, says Dr. Morgan. He likes Brodie's stocking in the treatment of inherited syphilis.

In the Appendix, Dr. Morgan speaks in favour of the Contagious Diseases' Acts, and makes some good suggestions. The work is full of matter and should be read by all practitioners. Whether they agree with the conclusions or not, all must admit that Dr. Morgan's work is an excellent one.

◆

Obituary.

DR. GEORGE E. DAY, M.A., LIC. MED. CANTAB.; F.R.C.P. LOND., &c.

AFTER more than ten years' suffering, not only borne with patience, but brightened with Christian courage, and a serenity of mind which no bodily pain seemed able to overcloud, there passed away from us one who has left his mark upon the world of medicine. Albeit many of his fellow-workers scarce knew whose was the hand that wrought so much, or whose plume was ever in the fore-front of the battle. So much, and that often his best, was written by Dr. Day anonymously, that even those best conversant with Medical and scientific literature might be pardoned for not knowing half the services his facile pen and clear head have rendered the Medical public. It was known that he had written "A Practical Treatise on the Diseases of Advanced Life," "Chemistry in its Relations to Physiology and Medicine," and most of the Medical articles in *Chambers's Encyclopædia*, as well as many others on allied subjects; and that he had edited or translated several works for the Sydenham and Cavendish Societies, including those of Simon and Lehmann on "Animal Chemistry," and Rokitansky and Vogel on "Pathological Anatomy." It was also known that he often contributed to the *Medico-Chirurgical Review*. But it was not so generally known that he also wrote many contributions to general literature, and furnished articles for Transatlantic journals. During the last year of his life, and the tenth—almost eleventh—of enforced confinement within four walls (brought on by the terrible accident of 1861, when he fell into a shaft long since disused while botanising), he wrote many graceful articles for *Once a Week*, furnished a quarterly report for Hammond's *Journal of Psychology* (New York), besides other articles. "I have been a hard worker all my life, and I shall die in harness," were almost his last words, and true they were. It is no exaggeration to state that Dr. Day was one of the most learned men modern times have ever known.

He was born on the 4th August, 1815, and died on the 31st January, 1872, nominally of bronchitis, really of the effects of the terrible accident which led him to resign the Professorship of Medicine at St. Andrew's. He studied at Cambridge, where he came out 29th Wrangler in 1837. In the autumn of 1841 he married Miss Ellen Buckton, daughter of the well-known London solicitor, James Buckton, afterwards Registrar of the Ruabon County Court. One son and two daughters survive of a family of six. In 1843 he settled in

Southwick street, Hyde Park, and for some five years the late Edward Forbes formed a part of his home circle. Whilst in London he was Physician to the Finsbury Dispensary, and the Western General Hospital, and lectured on materia medica at the Middlesex Hospital School of Medicine. In 1849 he was elected Professor of Medicine at the University of St. Andrew's. It is not too much to say that to him it is mainly owing that the degrees in physic of that ancient university were raised from being almost a reproach to a highly honoured position in the Medical world —*teste* our London and provincial hospitals and Schools of Medicine, and witness also the book-shelves of our Medical libraries. In 1861 he met with the before-mentioned accident; and although he took part in one or two subsequent examinations, was soon compelled to give up all exercise, and all work, but that of the brain and the pen, and soon after to leave St Andrew's for the mild climate of Torquay. She who knew him best writes of him in these touching words, as true as they are eloquent:—"He wrote as he read, on all subjects. He was the most learned, and at the same time the most humble man I have ever met,—generous in helping all who came to him, and most generous in giving the fullest honour to all his Medical and literary brethren. In his long illness, and often very painful physical condition, he never murmured. He was courteous to all about him, and grateful for every attention. . . . His last illness (a sharp attack of bronchitis) commenced early in January of this year. On the 29th he received the Holy Communion, and expressed his firm trust in God and the atoning blood of Christ, adding—'I have long known I could do nothing good of myself.' He then begged that his friends would be good to his wife and children when he was gone; and though he lived till the morning of January 21st, he scarcely spoke after."

Such was George Edward Day, the friend of Brewster, of Forbes, and of "many more whose names on earth are dark, but whose effulgent radiance cannot die."

We, still bearing the heat and burden of the day, or mingling with the festive crowd, cannot but re-echo the touching words of Shenstone:—"Heu, quanto minus est cum reliquis versari, quam tui menimisse!"

DR. JOHN MILLAR.

THIS gentleman, who on the 20th of December, 1871, in his thirty-first year, succeeded to the office of physician to the Edinburgh Fever Hospital, shortly after the death of Dr. Mackenzie, his predecessor, who died on the 26th Jan, having fallen a victim to his devotion to his work. He graduated at Edinburgh in 1863, became a Fellow of the College of Surgeons in 1867, and of the College of Physicians in 1869. He visited the Medical schools of Paris, Berlin, Vienna, and St. Petersburg. He held several other appointments.

DR. BAIRD, F.R.S.

THIS gentleman, since 1841, has been in the Zoological Department of the British Museum. He died on Saturday, the 27th January, after a lingering illness. He was the author of an important work "Natural History of the British Entomostraca," it was published by the Royal Society in 1850.

In London, last week, there were 1,524 deaths registered, being 121 below the average. There were 480 deaths from diseases of the respiratory organs, showed a further decline upon the numbers in recent weeks.

The ratepayers of Birmingham have approved a plan for dealing with the sewage of that great town, which will involve an expenditure of £5,000,000.

Correspondence.

ON THE INFLUENCE OF ERGOT IN MIDWIFERY PRACTICE.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I had hoped to remain silent, but finding by your issue of the 24th ult. that a fresh correspondent has entered the field and taken up new ground on whose strictures—with your permission—I beg to offer a few remarks. He says, "To me it seems an extraordinary proceeding to leave a woman with a fœtus in utero labouring under the influence of several doses of ergot for the space of three days." Again, "I am grieved to think what it might not, or rather ought not have produced in a case where several doses of it were administered and so left for a space of three days," and as a test of its therapeutic action he brings forward a solitary case, and one only, that of a woman of "fat, fair, and forty," in her first confinement, and so far as the labour itself is concerned, one of the most ordinary description. There are some interesting features however in the case not to be met with every day.

After telling the doctor that her sickness was severe, and that the pains were strong, he addresses her in these consolatory words: "to take them quietly, for that it was a considerable time since you took ill, (one would suppose) but no, it is literally thus:—For that it was a considerable time before she would be delivered." Dismiss your printer at once Sir, (surely it must be an error of his), or he will bring merited disgrace on a hitherto unimpeachable journal, but pardon me, perhaps you keep him for the very purpose—like the inevitable clown in the circus—of making your readers laugh (*a*), and who so much in need of a hearty laugh as the hard worked members of the medical profession? Keep him on then.

The waters having been discharged, a singular discovery was made. "I could now find the ear under the right pubis, and anterior dips of os down between head and it." Well! well! how unaccountable sometimes the "freaks of nature" are, and how naughty and rebellious too, though repeatedly urged to keep her own side.

Where in all the world, I would ask, should the uterus be if not "between" the head of the child and pubes? Who, again, I would ask, that has had any experience in midwifery practice, but must have frequently witnessed in *primapari* cases—indeed, it may occur in any case—the uterus remaining quiescent for a longer, or shorter period, only to resume its functions with redoubled energy, quite independent of a homœopathic dose, "forty drops" (equal to about twenty-five minims) of etherial tr. of ergot. However, a "semi-asphyxiated" child is born, and "having cut the cord," &c., many eminent authorities in the Profession would, under the circumstances, have hesitated before separating the cord, until the circulation had been well established, under the new order of things, which would, in all probability, have rendered the hydropathic treatment unnecessary—which system (by the way) was reversed in this instance by the cold plunge first. But to return, let me inform Dr. McKeogh of a fact of which he is either seemingly, or wilfully ignorant, namely, that the utmost ill effects produced by an ordinary dose, or, "repeated doses" of ergot (*b*), is sometimes, not always, a little nausea, or sickness of stomach which soon passes off; its power for evil on the fœtus—when the uterus is not excited to action by it—is absolutely *nil*.

I trust this explanation will help to mitigate, if not, altogether dispel his grief. And now Sir, lest it might be supposed from a former letter of mine in reply to Dr. Luther's critique, that I am averse to manual, or instrumental aid, in difficult or dangerous cases of midwifery, I take this opportunity of stating, that the very reverse is the fact. The rule in my dispensary district, which is a very extensive one is, that I am not called upon to attend, except in difficult, or dangerous cases, consequently it has fallen to my lot to encounter bad cases only. There is not a difficult operation in midwifery that I have not performed, save, and except, the "Cæsarian," often single-handed, in the middle of the night, when to have delayed for an hour or two for the purpose of procuring assistance, would have involved the certain death of both mother and child. I have the gratification of meeting the subjects of

---

(*a*) Alas! that it should be so often at our own expense.

(*b*) Three times twenty grs. was the amount of powdered ergot given by me—in a little cinnamon-water—in the space of two hours.

such operations frequently, and most of them have since borne children.

Thank God the process of parturition is a natural one, and it is but seldom (comparatively speaking) we are called upon to interfere, and woe be to the man who through ignorance or caprice inflicts unnecessary punishment on either mother or child, unless there be strong indications to the contrary.

This rule I have laid down for myself, others may pursue a different course if they think fit, I can only hope they are few in number, and that their bounds for mischief may be circumscribed.

With fraternal greetings to your correspondents, and my critics, I now take my leave, thanking you, Sir, for the space in your journal which I was reluctantly compelled to occupy in self-defence.

I have the honour to remain, Sir,
Yours, very truly,
R. G. Sheil, M.D.

Killyleagh, 30th Jan. 1872.

ABSENCE OF TUBERCLE IN ICELAND.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Dear Sir,—I think it right to state that the averment as to the absence of tubercle in Iceland, incorrectly ascribed to Schleisner in the *Westminster Review*, is fully refuted in my treatise "On Consumption."

As you have yielded fresh currency to this error in the recent edition of your great work "On the Practice of Medicine," it is only proper to draw your kind attention to the circumstance. In the sequel to the above treatise, entitled "Consumption and the Breath Rebreathed," which the Messrs. Longman's at this moment are bringing out. I have again referred to the very serious misstatement in the *Westminster* and its unfortunate adoption, as I must consider it, by you.

Trusting to your courtesy and fairness for the rectification of an error calculated to disserve the interests of science and of truth. I remain, dear Sir,
Your very faithful Servant,
Henry MacCormac, M.D.

Belfast, February 8th, 1872.
Sir Thomas Watson, Bart., M.D.

HOMŒOPATHIC RECANTATIONS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—In your edition of Feb. 7 there appears an article headed "Homœopathic Recantations," which contains some fragments of an article lately written by me in the *Monthly Homœopathic Review*, and which ends with a personal enquiry, "Whether Mr. Allen still continues to call himself a homœopath?"

Justice and courtesy alike entitle me to answer your article, and reply to your question.

In my article I merely discussed the relative superiority of high or low *attenuations* of homœopathically selected medicines.

Is it possible that the Editor of a Medical Press and Circular does not know that the amount and potency of a homœopathically selected medicine have always been open questions? and that homœopathy means, not the selection of an atom more or less of any medicine, but the treatment of disease by remedies selected according to their power of producing symptoms similar to (not necessarily identical with) the symptoms of the disease? The mere amount of the dose is, and always has been, an open question.

In the article, of which you have reprinted some fragments, I discussed this open question. But I in no way "recanted" my faith in homœopathic law, of the truth of which I am as certain as I am of the fact that the earth moves round the sun.

I merely wrote that I had come to prefer low homœopathic dilutions to higher homœopathic dilutions. But I in no way cease to be a homœopath, nor do I ever choose a remedy, save on purely homœopathic principles.

After all, what are the low attenuations of which I speak? One or two drops of a tincture extended in a tumbler of water, of which spoonful doses are given at convenient intervals.

An honest allopath would regard such doses as useless; but. homœopathically selected, such doses are regarded by us as very powerful, and are called low attenuations. Those, however, who select them are no less homœopathicians than the practitioners who select the 200th or the 10,000th potency.

In a word, Mr. Editor, you have either stumbled upon, or purposely adopted an old artifice, by means of which you hoped to throw dust in the eyes of your readers. You have begged the question; you are guilty of "petitio principii;" you have *assumed* that I "recant," and under pretence of "gladly welcoming" my "emergence" from a position which a perusal of the entire article must convince any rational being that I have never quitted, you have tried to throw a stone at homœopathy.

It is too stale a controversial trick to set up your man of straw and then knock him down. If you will discuss any question, let us discuss it fairly; open your columns to me, and I will do some thing more than convice your readers that a homœopath makes no recantation in preferring even the lowest homœopathic attenuations.

I would only add now, that in youth I carefully studied allopathic medicine; that in early manhood I became convinced of the inutility of allopathic treatment; and that, with maturer experience, I became a convinced and practical homœopath. Every hour that I live increases my most assured and certain conviction that, in homœopathy is found the best and quickest and safest treatment of every kind of disease. C. Allen, M.D.
Graduate of Oxford, Paris, and Philadelphia.

4 Rue Duphet, Paris, Feb. 12, 1872.

Medical News.

The Chair of Forensic Medicine at King's College, London, vacant by the resignation of Dr. Guy, has been conferred on Dr. David Ferries, Demonstrator of Practical Physiology in the College.

Mr. Ruskin's Election as the Rector of St. Andrews University has been declared illegal on account of his professorship at Oxford, so that the office has fallen to Lord Lytton, who was second on the lists.

At the last meeting of the Sanitary Committee of the Lincoln Union, the Medical Officer of the Local Board, having reported to the Committee that two un-vaccinated children, suffering from small-pox, were brought from Nettleham to the Hospital at the Lincoln Workhouse on the 12th inst., in an open cart resolved that it is the opinion of the Committee that this conduct is highly reprehensible and dangerous to the public health, and the Clerk is instructed to take proceedings against any person or persons infringing the law for the future." This is as it should be.

NOTICES TO CORRESPONDENTS.

CONTRACT DRUG PURCHASING.

To the Editor of "The Medical Press and Circular."

Sir,—My attention having been directed to the leading article in your Journal of the 31st ult., headed "Contract Drug Purchasing." in justice to our firm, I wish to set you right on some points upon which, no doubt, you have been misinformed, viz.: "that to obtain an Irish Union it is necessary for a contractor to fix his prices at the minimum, as his only hope of obtaining the contract." Now inasmuch as we are supplying many unions, we beg to inform you that in no case have we practised this device, and yet we have the pleasure to supply many Unions throughout this country. For submitting our tenders we solely based the prices in our tender on the reputation of our House, and from this principle we are not likely to deviate. We have the pleasure to hand you one of our new issue of our price drug list, as by your leading article the Medical Profession might be led to suppose that there was but one house in the trade who have ever published a monthly price current, whereas we have done so for many years.

I may also remark that some of the prices recapitulated in your leading article are incorrect. Yours respectfully,
John Geo. Boileau.
(For Boileau & Boyd).

Bride street, Dublin.

E. R.—We are glad to hear that you received our packet. Thanks for your letter and for promise. You will have heard that the other matter is concluded.

Dr. Birchenall, Macclesfield.—Aught but partisanship in the conduct of the Journal to which you refer, is understood to be by those best acquainted, the rule, not the exception. Your letter was too late for our present issue.

JOH. HOFF'S MALT EXTRACT.
Patronised by the Principal Courts of Europe,
The Military and Naval Hospitals of the Continent, as well as by the most eminent Physicians, and by the Nobility and Gentry of England and Europe.

HOFF'S MALT EXTRACT is beneficial in cases of Weakened or Diseased Digestion; in obstinate Catarrhs and Coughs; Hoarseness; Catarrhal Diseases of the Bronchial Tubes; in cases of incipient and progressive Tubercular Consumption; and in cases of Bodily Weakness and Exhaustion.

HOFF'S MALT EXTRACT has, by its own intrinsic merits, earned for itself a reputation, as a curative and invigorating remedy, not surpassed by any other. It possesses a very agreeable flavour, and is adapted to the most enfeebled digestion.

HOFF'S MALT EXTRACT has recently received additional support from Testimonials emanating from Physicians and other official persons engaged in the late war. These Testimonials are, in their high character, unsurpassed by any that have been brought before the public.

HOFF'S MALT EXTRACT. Pamphlets, with Testimonials from Emperors, Kings, Princes, and eminent Physicians, may be had (post free) at the sole Depôt, 57 KING WILLIAM STREET, CITY, LONDON. Price 21s. per dozen, carriage free; or 1s. 9d. per bottle.

CASTLEBAR UNION.

CASTLEBAR DISPENSARY DISTRICT.

NORTH DIVISION No. 2.

Comprising the ELECTORAL DIVISIONS of ADDERGOOLE, BALLYNAGORAGHER, PONTOON, BURREN, and CROAGHMOYLE.

MEDICAL OFFICER WANTED for the above Division.

Notice is hereby Given, that the COMMITTEE OF MANAGEMENT of the above Dispensary District will, at their Meeting, to be held at the Board-room of the Castlebar Workhouse, on WEDNESDAY, the 28th FEBRUARY, 1872, at the hour of Eleven o'clock A.M., proceed to the appointment of a properly-qualified Medical Officer for the above Division (he will have to reside in the Electoral Division of Ballynagoragher), at a salary of One Hundred and Ten Pounds a year, exclusive of Registration and Vaccination Fees.

Candidates must possess the qualifications set forth in the Orders of the Poor-law Commissioners.

Applications, with Testimonials, to be addressed to the Secretary, JAMES FAULKNER, Esq., Castlebar, up to Ten o'clock on the 28th February, 1872, at which hour the Candidates must be in attendance.—By Order,

ROBERT J. NIXON, Clerk of Union.

Board-room, Workhouse, 31st January, 1872.

FIRST-CLASS PRACTICE FOR SALE.—Price £400. Average nett income, £700.—In consequence of the retirement of the present incumbent, who has been in the practice upwards of 30 years, a very exceptionally good opening occurs. The practice is situate in the North-east of England in a first-class farming and agricultural district, with good fees, &c. For particulars apply to A. A. T., care of Messrs. Baillière and Co., Publishers, 20 King William street, Strand, London.

Established 1848.

PROFESSIONAL AGENCY AND MEDICAL TRANSFER OFFICE.

50 LINCOLN'S INN FIELDS, W.C.

J. BAXTER LANGLEY LL.D. M.R.C.S., F.L.S.,

&c., (KING'S COLL.), and Author of VIA MEDICA,

Has always upon his books a large number of desirable investments and available Appointments for negociation.

The business of the Professional Agency is based upon the general principle that no charge is made unless work has been done and services rendered.

No Commission charged to Purchasers.

Full information as to terms, &c., sent free on application.

Office hours, from 11 till 4; Saturdays excepted.

PRACTICES AND PARTNERSHIPS NOW OPEN for negociation (in addition to those advertised in Dr. Langley's List, (which is sent post free on application).

Y 402. SOUTH EASTERN COUNTIES. An excellent Country Practice, in a small town. Receipts £900 a year; appointments £300. The residence is very convenient, contains twelve rooms, with gardens, greenhouses, &c., rent £40. A thorough introduction can be given, and the whole practice is believed to be transferable.

Y 403. In a LARGE TOWN on the SEA-COAST. A well-established Practice, yielding £700 a year; there is scope for a large Consultation Practice by a gentleman of high qualifications. Usual midwifery fee £2 2s., and upwards. All the practice lies within a radius of one mile; no dispensing; no assistant required, The house is situate in the best part of the town; contains eleven rooms; rent £35. An efficient introduction can be given.

Y 404. The nucleus of a LARGE PRACTICE, in a pleasant district of WORCESTERSHIRE. Receipts average £250 a year; patients good class; expenses very small. To a gentleman with limited capital, it affords an unusual opening.

Y 405. DORSET. For immediate disposal upon easy terms. A well-established Practice, realising upwards of £400 a year. Patients good middle class; Appointments yield £100; expenses very low; part of the premium may be paid by instalments.

Y 406. MIDLAND. A well-established Practice, yielding upwards of £1,100 a year. Appointments and Contracts £540; all transferable to a suitable gentleman. One assistant and two horses kept. Patients good middle class; premium £800, of which part may be left on security. The Incumbent having entered upon a partnership elsewhere desires to effect an immediate arrangement.

Y 407. GLOUCESTERSHIRE. An old-established Practice, yielding upwards of £1,000 a year. Patients good middle class; midwifery fees £1 1s., and upwards; very little opposition. The house contains ten rooms, with every convenience. Ill-health the cause of retirement.

Y 408. In a MANUFACTURING DISTRICT. An easily transferable Practice, producing £400 a year, and conducted with very small expense; premium £250.

Y 409. SPECIAL PRACTICE in LONDON, established 40 years. The receipts have been about £1,000 a year, the Copyrights of two works can be transferred and would carry, it is believed, a part of the connection. The house is extremely well situate for practice, and is held on lease at a very low rental; premium for the whole, £500.

Y 398. LONDON, N. For immediate disposal in consequence of serious illness, a practice, the average receipts from which have been upwards of £1,000 a year. The house is situate at the corner of two important thoroughfares, with an excellent neighbourhood. There are no poor patients; the house is exceedingly convenient, with facilities for a large business in an open surgery if desired; the practice has been well attended to by a *locum tenens*, prohibited from practice on his own account; midwifery fees £1 1s. and upwards; liberal terms will be conceded to gentleman of experience, but no application can be entertained based upon future receipts.

A FEW PRACTICAL REMARKS ON THE TREATMENT OF CATARACT.

By George Critchett, F.R.C.S.,

Senior Surgeon to the Royal London Ophthalmic Hospital, Moorfields.

(*Continued from* p. 19.)

We will now take into consideration the important modifications that have during the last few years been introduced into the method of extracting cataracts. The modern plan is usually known as the "linear extraction," though for reasons hereafter to be stated, I think the term "*curvilinear* extraction" would more accurately express the form of incision. Previous to describing this operation in its matured and perfected state, and as it is performed with certain slight modifications by most of the more advanced modern oculists, I will endeavour to trace the successive stages through which the operation has passed before it reached its present development. The first idea of extracting a cataract through a small opening in the cornea is no doubt due to Mr. Gibson, of Manchester, who published a paper on the subject in 1814. It had, however, fallen into disuse until it was revived simultaneously by Von Gräefe and by Mr. Bowman. The employment of this operation was in the first instance limited to soft cataracts and the opening in the cornea was small, such in fact as would be made by the introduction of a broad needle. Gradually, however, Professor Gräefe began to enlarge his incision to the size he usually employed in performing an iridectomy, and in certain cases of cataracts of medium density that could be readily broken into fragments. After making a moderate-sized opening with the spear-shaped knife, he performed iridectomy, and removed the lens by the successive introductions of a small spoon. This spoon the Professor has shown me, it very much resembles an ordinary teaspoon in shape, and is interesting as having initiated a mode of extraction that as we shall see for some time held its ground, though it has been since abandoned. I believe that Von Gräefe had only employed this method on a few occasions, and in a tentative spirit, when his assistant, Herr Schüft, or Waldow as he is now called, published a pamphlet, in which he advocated a more extended employment of the linear method of extraction and the use of a peculiar kind of spoon of an oval dish-like form, with abrupt edges, which by successive introductions should bring out a load of lens within it, so as gradually and piecemeal to remove as completely as possible the entire cataract. It was this pamphlet that first drew my attention to the subject of modified linear extraction, as it was then called. I at once procured the "Schüft spoon," as it was then denominated, and I believe I was the first to perform the operation at Moorfields Hospital, as he recommended. I confess that I was mentally predisposed towards any modification of the flap extraction, more especially in some of the restless and somewhat unruly hospital patients. In performing this operation I usually placed the patient under the influence of chloroform. The early steps of the operation were similar to those for an ordinary and rather large iridectomy, and then after freely opening the capsule I brought out spoonful after spoonful until I had removed the entire cataract, or such portions of it as could be induced to enter the spoon. Certain peripheral fragments would often remain concealed behind the iris, and would subsequently be washed into the pupil when the aqueous was resecreted. My early attempts with this operation were satisfactory and encouraging, but subsequent failures and further reflection convinced me that there were some serious sources of danger that could be materially diminished, if not entirely removed. I also found that for certain forms of senile hard cataract it was quite inapplicable. The objections, as we now regard them from the vantage ground of increased knowledge and experience, are very obvious, and even at the time they were sufficient to stimulate efforts at improvement; but with all its faults the operation had the merit of setting the mind at work upon a new track. It soon began to impress itself upon my mind that there were two directions in which this operation was capable of improvement, the one had reference to the size and form of the incision, the other to the form of the spoon.

The opening made in the cornea by an ordinary spear-shaped knife, as in the operation of iridectomy, is obviously too straight and too limited to allow of the escape of a cataract of ordinary size and density, and the size and form of the schüft spoon increased the difficulty by interposing additional bulk to the cataract as it was in the act of making its escape. The first of these objections, that which had reference to the size and shape of the wound, I endeavoured to obviate by enlarging the incision either with the knife as I withdrew it, or subsequently with scissors, in such a way as to give a slightly curved extension to the wound at either extremity in the cornea-sclerotic tissue, so as to form a slit of sufficient size to allow of the escape of a fully developed hard cataract. It must, however, be admitted that at this stage of our labours we often experienced some difficulty in effecting the escape of a large, hard, fully-formed senile cataract through the incision, even after it had been enlarged; though it was a manifest improvement upon that formed in the ordinary way by an iridectomy knife, the objection to which is that it makes a straight incision. We had, in fact, passed from one extreme to another—from a large or semicircular section of a small circle to a linear one, which must necessarily be limited by the small extent of the textures in which it could be made.

The second objection, viz., the size and shape of the spoon, I endeavoured to remove by modifying its form materially, taking away the edges so as merely to have a thin metallic plate, curved so as to correspond with the posterior surface of the lens, sufficiently narrow to enter the opening readily, and with a little receding portion at the extremity so as to impress itself into the posterior surface of the cataract, and exercise a traction force as it emerged from the interior of the eye. The advantages of this spoon, as contrasted with the one previously in use, were sufficiently obvious; it occupied but little space, could be readily insinuated behind the cataract between it and the hyaloid fossa; it had no tendency to break up the lens into fragments, but removed all the solid unclean portion, and even the cataracts in an entire and unbroken state, when it was sufficiently firm and hard. Although the spoon is now for the most part dispensed with, yet in those exceptional cases in which it is still required, this form of spoon is the most convenient and available. In consequence of these modifications that were introduced into the method of performing the operations the average of success was brought up to the standard of the flap extraction, and whilst there were certain admitted drawbacks, there were also some manifest advantages that entitled the operation to rank amongst the established methods of proceeding. The weak points of the operations were the difficulty in making the wound of a sufficient extent to allow of the ready escape of the entire cataract; the liability to fragments remaining concealed behind the iris, and in the area of the pupil, or between the lips of the wound, the difficulty of passing the spoon behind the cataract and between it and the hyaloid membrane without rupturing the latter and causing an escape of the vitreous humour—a liability to bruising and stretching of the wound, in the immediate vicinity of the ciliary region, whose injury is apt to produce unpleasant results—a troublesome form of traumatic iritis, or the formation of a secondary membranous cataract necessitating the performance of a subsequent operation. It must also be admitted that the iridectomy and the change in the curvature of the cornea renders the eye so operated on a less perfect optical instrument than after a complete flap extraction. On the other hand the advantages were sufficiently obvious, but these I shall have occasion to dwell upon in a subsequent part of this paper. The operation in this amended form was submitted to an extended experience at the Moorfields Hospital by my distinguished colleague, Mr. Bowman, by myself, and others, and with such favourable results as to entitle it to rank amongst the safe and eligible methods of removing cataract. Matters had reached this point when I read a paper upon the subject at the Ophthalmic Congress in Heidelberg, setting forth the advantages of the linear method of extraction with the modifications recently introduced. I found that the operation, as described by Schüft, had fallen into great discredit with my continental *confrères* on account of the large average of failures, and was for the most part given up, and I believe I was the humble instrument just at that juncture of rescuing it, and of establishing it on such a basis as, with the aid of further important modifications, must place it amongst the most valuable methods yet discovered for the removal of cataract. Amongst other important results of my paper may be reckoned the interest it excited in the mind of our much lamented *confrère* Von Gräefe. He visited England chiefly to witness the operation and to watch the results, and it was my privilege to co-operate with him in these investigations, and I know that he returned to Berlin much impressed with the success of the operations he then saw. He subsequently tried it on an extensive scale at his own clinique, and working out still further the idea that the wound should be of sufficient size and of such a shape as to allow of the escape through it of a firm hard cataract, he introduced two important modifications—he altered one instrument and dispensed altogether with the use of the other. He found that the spear-shaped knife had some serious disadvantages; the wound was straight, or very nearly so, and was limited in size by the width of the instrument at its broadest part; he therefore adapted a narrow knife or needle knife, as it is called, by means of which he could determine the point of entrance, the point of emergence, the size and the shape of the wound, and the exact tissue in which it should be made. This was an important advance in the operation, and it was soon found that by giving a curvilinear form to the wound, as indicated in wood cut (Fig. 1 and Fig. 2A) by the dotted lines corresponding to the curvature of the antero-posterior surface of the lens, and by giving an extent by measurement rather greater than that of the lens itself, the cataract could be expelled by making gentle pressure, just as in the ordinary flap extraction, and without the introduction of a spoon. Two very important points are thus obtained—1st, a wound, that by its curvilinear form, and by its extent, would permit of the exit of the cataract, and yet would keep its edges in apposition, even under circumstances of strain and pressure; 2ndly, the avoidance of the bruising and irritation inevitably resulting, more or less, from the introduction of a spoon of any kind into the interior of the eye. On the one hand the straight linear limited incision of the Schüft, and on the other the semicircular section of the cornea were avoided. The former is unsuited to allow the escape of the cataract unless with force, bruising and comminution, and without the aid of a spoon. The latter, as I have already explained, leaves the eye unsafe and the union problematic. The form and extent of the incision being thus established we may define it to be the segment of a circle double the size of the cornea (Fig. 2A) and about one-fourth

FIG. 2.

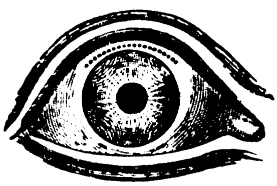

FIG. 2A.

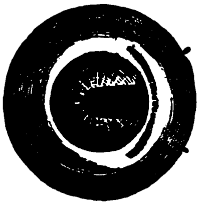

or one-fifth of its circumference, as indicated by the dotted lines in the wood-cuts. It is of some importance, then, to formulise the curvilinear incision, because it gives to the operator a precise idea of what he is about to do, and to the student a clear conception of the operation, and a definite aim for his studies; and as I think it may be safely predicted that the curvilinear section is destined ultimately to supersede the flap or semicircular section, and to be the only one taught in the schools, the more accurate the definition can be made the better. It is quite possible that some of those who have long practised the flap extraction and have acquired considerable manual dexterity therein may still continue to perform it, but it is scarcely conceivable that surgeons who are just starting upon an ophthalmic career should adopt so difficult an operation, and one so full of serious objections, when a far safer and easier one has been discovered. For my own part, though for years I practised flap extraction with fair average success, I never desire again to operate by that method.

Having thus defined the form and extent of the curvilinear section, the next point to determine is the situation of the wound. There are two points to consider in reference to this question, viz.,—whether the incision should be very peripheral and should traverse the cornea-sclerotic tissue, see Fig 2, or whether it should chiefly traverse the true corneal tissue only slightly encroaching on the cornea-sclerotic element at its two extremities, see Fig. 3. There is also a third situation in which it may be placed, but it would only complicate the question to bring this in at the present time, as it belongs to an entirely different kind of operation. It is probable that some difference of opinion will prevail as to whether the cornea-sclerotic or the corneal section should be preferred, each has advantages and dangers which the other lacks, and nothing but careful observation and extended experience can decide the point, and it may be that the question need never be decided but both methods may be retained—further knowledge may demonstrate that in some constitutions the fibrous tissue and in others the cornea may be the most safely wounded, and thus by selecting from the two situations better statistics may be obtained. Von Gräefe was in favour of the peripheral or sclerotic-section, and it is the one that has been the most extensively followed; it has the advantage of facilitating the escape of the cataract, of avoiding the danger of suppurative inflammation and of preserving the normal curvature of the cornea. On the other hand, there is greater risk of losing vitreous humor, of having some entanglement of iris in the angles of the section, and of bruising the delicate ciliary nerves, thus entailing the severe penalty of protracted iritis or a form of sympathetic ophthalmia. When the cornea is chiefly involved in the section, the expulsion of the cataract is attended with more difficulty, and the risk of purulent inflammation is greater. The curvature of the cornea is also more liable to be changed, but the iris is less likely to be entangled in the wound, and sympathetic ophthalmia or iritis less frequently occur. It will be interesting in the next place to weigh candidly the advantages of the curvilinear as contrasted with the flap extraction, and also to consider what are its weak points, and if they admit of being further modified or avoided.

LECTURES ON DERMATOLOGY.

Delivered in the Royal College of Surgeons of England, in February, 1872, by

ERASMUS WILSON, F.R.S.,

Professor of Dermatology to the Royal College of Surgeons of England.

LECTURE II.

THE history of the world, in reference to disease of the integument, brings before us some curious examples of pathological phenomena. In the north of Italy there is met with, amongst an ill-fed and badly housed population of the labouring class, an erythema of the uncovered parts of the skin—for example, the hands, the legs, and the neck—which is attributed to the sun, and is therefore called the *mal del sole.* This affection is essentially a paralysis of the cutaneous nerves, and a consequent atrophy and hyperæmia of the integument. The disease is named *pellagra,* and the affection of the nerves of the skin is only the prelude to more serious changes in the central nervous system, ending in mania and death.

Now it so happens that we occasionally meet with this combination of atrophy and hyperæmia of the skin in other countries, and in a better nourished class of persons, and independent of the deeper and more important changes of the nervous system which issue in disease of the brain. No. 103 is a model representing *erythema pellagrosum* as it is sometimes seen in Paris. The patient was thirty-six years of age, and the erythema is presented to us as a circumscribed circular blotch, extending from the middle of the first phalanx of the index finger, middle finger and thumb, to above the wrist in one direction, and from near the ulnar border of the hand to the radial border in the opposite direction. The redness is pretty uniform over the whole area, and the latter is bounded by a red margin, which is blotchy from point to point, indicating the presence of new centres of hyperæmiation.

No. 104 is a coloured photograph of the same affection, occurring in a gentleman who had spent many years of his life in India. A careful examination of the model and of the photograph is sufficient to convince us of the identity of the disease. The patient was debilitated and dyspeptic, his complexion tawny and yellow, and countenance dejected. His engagements in India demanded an excessive use of the hand in writing, to which he added the occupation of an amateur artist, and in consequence of the loss of power which resulted he was thought to be the subject of "scrivener's palsy." The erythema on the dorsum of the hand had been four years in existence; it began as a small circular patch, and increased gradually to its present extent. It was preceded by excessive sensibility of the skin with neuralgia, and upon this followed insensibility, with loss of power of motion of the hand, and especially of the thumb.

Unhappily we possess, as yet, no specimen of *purpura,* or, as it may be termed, erythema porphyricum, or purpureum. But nearly all the examples of erythema which we have heretofore examined may be regarded as leading up to that affection. *Purpura* is an erythema associated with the escape of blood from the capillary vessels so as to produce a purple spot in the skin. The spot may be a mere speck, or *stigma;* it may have the appearance of a flea-bite or *petechia,* that is, a central point surrounded by a halo of a brighter tint; it may occur in stripes or wheals, which are termed *vibices;* or it may present itself as a diffused blotch or *ecchymosis.* The colour of purpura will vary with its age, ranging from bright crimson to purple black, and its figure and extent with the degree of vital resistance of the tissues. The crimson and purple hues of the roseate erythema, Nos. 98-99, and also of the example of erythema copaibicum, may be taken as showing a leaning towards purpura; a similar inclination is evinced by the bruise-like stains left in the skin at the decline of several of the erythemata ; while, on the other hand, the relationship of purpura to urticaria is manifested in the variety of the former affection, which is termed purpura uricans.

Since as yet we have no specimens of erysipelas in the dermatological collection, I shall pass it by somewhat cursorily. Erysipelas is an erythema aggravated in the intensity of all its symptoms ; there is more local heat and uneasiness ; the integument is more swollen and more deeply infiltrated ; the migratory habit is more conspicuous ; often the infiltrated fluids exude beneath the epidermis, giving rise to blebs ; and the constitutional symptoms are generally severe, and often serious. We scarcely know a disease more frightful in its aspect than an erysipelas of the head—the part attacked hugely swollen, the eyes closed, the features deformed and seemingly obliterated, and the mind obscured by a low muttering delirium. Yet all these symptoms have been seen to melt away by a treatment which is justly regarded as specific in erysipelas, namely, twenty minim doses of the tincture of the perchloride of iron, administered every two hours. Of course this treatment must be preceded by a clearance of the *primæ viæ*, and the regulation of the functions of digestion and assimilation.

Erysipelas is always a grave disease, and there can be no doubt that many cases of inflammation of the skin, accompanied with redness and swelling, are presumed to be erysipelas, which, in reality, are nothing of the kind. Very commonly we hear of an erysipelas of the head which turns out to be a herpes frontalis, and still more frequently our patients make complaint of an erysipelas of the eyelids or ears, recurring spring and fall, or even every few months, which is obviously nothing more than erythematous eczema, attended with heat and considerable swelling ; the latter symptom to the extent of puffing up the eyelids and closing the eyes.

Urticaria.

As the nerves enter for a large share into the structure of the skin, while they especially govern its circulation and sensation, it would be difficult to select any cutaneous disorder in which they do not take a certain, if not a very conspicuous place. Occasionally morbid phenomena are presented to our notice, in which the nerves alone seem to to be the seat of disorder. Such are the instances of deranged sensation named prurigo and pruritus, and these, by common consent, have been denominated *neuropathic affections*. But these affections implicate one only of the functions of the nerves, namely, sensation ; while their motor function is not likewise included. A blush is the result of a neuro-motor influence, in which neuro-sensation can hardly claim a share, and a chronic erythema may persist, without any sensation whatever, for an indefinite space of time. It becomes necessary to take these physiological considerations into our council when entering upon the investigation of so remarkable an affection as urticaria. Its name is founded on its neuro-sensitive qualities, while its neuro-motor nature is evinced by the hyperæmia with which it is always accompanied, and which, from its analogies, has detained it in the family of the erythemata. By some dermatologists urticaria has been claimed as belonging to the group of neurotic or neuropathic affections ; but the most that can be said in favour of that claim is, that it is only semi-neurotic, and indeed scarcely, if at all, more neurotic than other members of the erythematous family ; while it differs from prurigo even more widely than it does from simple erythema.

Urticaria is a singular compound of itching, tingling, and burning, with redness, prominence in the form of small bosses and wheals, and evanescence. For several hours the state of the patient may be one of excessive torture from itching, tingling, and burning, with hyperæmic blotches and white protuberances ; the seat of torment varying its place from time to time, and occupying more or less extensively the surface of the body ; and yet, when a short time later the skin is inspected, not a vestige of the local appearances can be discovered.

Like other physical phenomena, of whatever kind, the special symptoms now indicated may present a variety in degree : the itching, tingling, and burning may be trifling or intense, the redness may be the same, the prominence more or less conspicuous, and the evanescence more or less complete. In the urticaria from irritant food—*urticaria ab ingestis*—hyperæmia and burning heat are present in the most aggravated form. In a case of neuropathic urticaria, which followed parturition, the tingling and shooting pains, with large, solid prominences of the skin, and very little hyperæmia, were almost unendurable, but ceased instantly on the sudden appearance of menstruation. Sometimes the urticaria is persistent, *urticaria perstans* as contra-distinguished from evanescent, *urticaria evanida ;* sometimes the pressure of creases of the bedclothes or that produced by wrinkling of the skin will give rise to wheals and pruritus ; and sometimes the light strokes of a pencil, as in writing upon the skin, is instantly followed by an uprising of wheals taking the form of the written characters. Some authors are of opinion that the bosses and wheals of the skin in urticaria are due to absorption of liquor sanguinis by the cells of the tissues ; but my own impression is that they are likewise produced by muscular spasm, and this view seems to be favoured by the sudden appearance and disappearance of the wheals.

Nos. 106 and 107 are drawings of chronic urticaria—the urticaria perstans of dermatological writers. The patient was a man, forty years of age, who had two consecutive attacks of the eruption, the first lasting nine and the latter six months. His illness originated with dyspepsia and rheumatism ; for this ailment he kept his bed during a fortnight, and as soon as he left his room was seized with urticaria. The eruption first appeared on his knees, then on other joints, and subsequently on the trunk of the body. The itching was always most severe at night, and abated in the morning. After obtaining some relief from the urticaria, he was seized with erysipelas of the forehead, beginning at the root of the nose, and spreading rapidly to the face and head ; the erysipelas was attended with violent delirium, and he died at the end of four days.

No. 108 is a water-colour study of a blotch of urticaria with a view to record its configuration and colour. In each of these examples it will be seen that the white boss rises out of the centre of an erythematous spot ; when it increases in size the centre of the prominence subsides, forming a yellowish area, encircled by a pale annular wheal ; the next change that takes place is the disappearance of a part of the wheal and the serpiginous growth of the rest of the circle constituting an arc of greater or less magnitude. At this latter stage, the hyperæmic redness is seen only along the convex border of the wheal, which it thus attracts, as it were, into the surrounding skin. Finally, both redness and prominence subside, and all trace of the eruption vanishes, rarely leaving behind it any vestige of its previous existence. Sometime a pale-coloured stain has been noted on the affected spot, and sometimes a slight pigmentary stain.

Among the more recent acquisitions made by our collection is a beautiful model (No. 517), by Baretta, showing a form of urticaria remarkable for the large size of its prominent blotches. The largest of these blotches measures nearly an inch in diameter ; they are all somewhat more protuberant at the border than in the centre, and each blotch is surrounded by a narrow band of redness. In several situations, three or four of the blotches are blended by their circumference.

In endeavouring to establish a diagnosis, from a therapeutical point of view, between the eczematous affections or eczemata and the erythematous affections or erythemata, I have been in the habit of saying that the first point which calls for our notice in the eczemata is the local affection, whereas the local affection is the last to need our assistance in the erythemata. In the case of the eczemata, we have very possibly to deal primarily with debility; but in treating the erythema the *first* indication, universally, is to act upon and clear the alimentary canal; *secondly*, to improve digestion and assimilation; and, *thirdly*, to prescribe such tonic remedies as the patient may seem to require. There is only one exception to this method of treatment, and that exception relates simply to time; the very instant the alimentary canal is thoroughly emptied in erysipelas, the tincture of the perchloride of iron may be commenced. Moreover, in chronic cases of urticaria, where the neurotic phenomena are the most conspicuous feature of the disease, small doses of arsenic may be found to be of the most valuable service.

The *local remedies* applicable to the erythemata are the dredging box; absorbent powders, such as oxide of zinc diluted with starch; or the oxide of zinc and calomine powder suspended in lime water.

Pruritus, and especially the itching of urticaria, will sometimes require, besides sponging with hot water, the warm bath, and a lotion of emulsion of bitter almonds, with borax or spirits of wine and hydrocyanic acid.

(*To be continued.*)

◆

SYPHILITIC DISEASES OF THE THROAT.

By Prosser James, M.D., M.R.C.P.,

Lecturer on Materia Medica and Therapeutics at the London Hospital, Physician to the Hospital for Diseases of the Throat, &c.

(*Continued from* p. 29.)

Syphilitic affections of the throat are so intimately and constantly associated with those of the mouth and nose, that they require to be considered together. This is not surprising when we remember how many of them commence in the mucous membrane, and that this tissue is continuous throughout these parts.

Lesions of the tongue may be named, but need not detain us long in this place. From its upper surface may be constantly traced masses of hypertrophied epithelium, like the mucous tubercles of other parts, and producing the well-known induration of the organ so often seen in constitutional syphilis. Ulceration of the tongue may also occur in a simple or specific form, as may the other syphilitic lesions (*a*). It is important to distinguish them from cancer, and the diagnosis is not always easy. I have seen some mistakes occur in this respect, and therefore first call attention to it here, leaving to a future occasion the full consideration of diseases of the tongue.

In the nose we find syphilitic lesions very common, and occasionally very intractable. Some of the affections resemble closely those of a non-specific nature. Of these may be named simple hypertrophy of the pituitary membrane, either with or without ozæna. This condition is mostly associated with a great liability to coryza, which is sometimes almost permanent. Strumous patients are unusually subject to this troublesome complaint, and constitutional treatment should be employed. With cod-liver oil and iodide of iron there is rapid improvement under the some lotions that have previously proved inert. Rhinoscopy should be employed both for diagnosis and treatment, but in even long standing cases nothing further may be discovered. Sometimes ulceration may be found.

The same state of affairs is common in syphilitic disease of the nose. There may be merely hypertrophied mucous membrane, giving rise to coryza, and this may be general or chiefly affecting the region of the inferior turbinated bones. It is, however, more common for ulceration to have commenced before the patient complains. At this stage the disease should not be neglected, for although now confined to the mucous membrane, it may even in secondary syphilis extend deeper and involve the cartilages and bones. Then there is sure to be ozæna, though that may have appeared earlier. It is, however, when the nose is invaded in tertiary syphilis that the graver lesions mostly occur. In these the deeper tissues may be invaded before the mucous membrane.

These patients frequently apply for relief from distressing ozæna and other prominent symptoms, of which the peculiar change in the voice is striking, and yet inspection only demonstrates the darker red of the membrane, with here and there erosions. In persons of a strumous constitution the destruction will be much more rapid than in others, and it is desirable to prescribe for the scrofula as well as the specific disease. When ulcerations and erosions can be brought into view by the mirror, they should be treated by its aid locally.

In a paper on ozæna which I read to the Medical Society of London last year, and an abstract of which has appeared in this as well as other journals, I entered more fully on this form of syphilitic disease of the nose, and do not therefore propose to repeat here the suggestions I have made as to its treatment.

I must, however, remark that syphilis may attack the deeper tissues first, or may extend to them. The former is more common in tertiary disease. This may begin as a gummatous periostitis; then, going on to caries and necrosis of the bones and cartilages, which exfoliate and give rise to great disfigurement, the disease may continue its ravages, and the unfortunate patient succumb to intra-cranial mischief.

Acute syphilitic periostitis is a very painful disease. The sufferings of the patient are exacerbated by warmth, so that it is common to consider its chief symptom as intense pain in the forehead and head more marked when warm in bed.

During the exfoliation of pieces of bone the discharge is most offensive. It used to be said that this only occurred from the abuse of mercury, but I have found it when I had reason to believe that the patient has been treated without that mineral, and may therefore be fairly considered one of the syphilitic phenomena. On the other hand it is desirable not to forget that caries may occur from other causes besides syphilis. The history will assist the diagnosis.

Sometimes the rhinoscope reveals very little to us, and yet there is a considerable amount of diseased bone, which cannot be brought within range of vision.

Before passing to the general plan of treatment of venereal diseases of the throat it may be as well to specify one or two points as to the management of nasal lesions, which have led me into this digression.

In addition to the steady use of the ordinary treatment we must resort to particular local measures suited to the case. Thus, abscesses which frequently occur are to be opened, and pieces of exfoliated bone are to be removed, just as if the disease were non-specific. So perseverance in the removal by the nasal douche of the fœtid discharge which accumulates must be employed. Alkaline or salt douches should wash away as much as possible, and afterwards a lotion of one of the permanganates should be frequently injected. As to the employment of mercurial lotions as washes, or in the form of spray, I have never used them; and after the sad consequences of the use of such a lotion in a far more justifiable way, it is not likely that this practice will be continued.

The constitutional treatment of syphilitic diseases of the tongue, mouth, and nose is the same as for that of the throat, respecting which I will add a few remarks.

In the treatment of all syphilitic throat diseases constitutional remedies should be employed. In laryngeal com-

---

(a) Since this paper has been in type, I have had the pleasure of examining the models and drawings of syphilitic diseases of the tongue in the Dermatological Museum of the Royal College of Surgeons. These were exhibited by Professor Erasmus Wilson in the last lecture of his recent course "On Dermatology," and are very excellent specimens of forms of disease which constantly come under my observation, and which I find more tractable than is usually believed.

plications of secondary syphilis these, with rest to the voice, by prohibition of talking, will mostly suffice, but they may be supplemented by such local means as seem indicated. It used to be said that laryngitis was the signal to pour in mercury. I prefer iodine and its salts. If ulceration occurs the inhalation of the spray of bichloride of mercury has been well spoken of, but one cannot measure the amount thus introduced into the system, nor can one tell the effect it may have on the individual patient. It seems in no way preferable to many other applications which have the merit of not being capable of doing so much mischief. The insufflation of mercurial powders may be discarded on similar grounds. The bath still holds its ground with some.

In tertiary syphilis iodide of potassium is the favourite of the majority, and I find it efficacious both in secondary and tertiary. But large doses must be given. The dose is in fact to be measured by the effect on the disease, and the ability of the patient to bear it. A patient may be kept under its influence, just short of iodism, for a considerable period.

Condylomata may be touched with nitrate of silver. In ulceration of the larynx iodine vapour should be inhaled. In some cases other local applications may for various reasons be preferred. Should œdema glottidis occur, scarification must be employed without hesitation. Loose pieces of necrosed cartilage should be extracted, or tracheotomy may be suddenly called for, or the patient may expire in the absence of surgical assistance. Small detached portions are sometimes expectorated, but with the laryngoscope to assist us we ought not to wait for this at the risk of sudden suffocation. The respiration may become so seriously impeded as to necessitate tracheotomy. This operation is indicated if the dyspnœa be serious, especially if there be violent paroxysms, threatening to destroy the patient, for he may easily die in one of them. Tracheotomy removes this immediate danger, and it also does more than this; it gives the much needed rest to the larynx, and enables us to cure the patient by such treatment local and general as may be needful, and by allowing time to lend us friendly aid.

It may happen that contraction of the rima glottidis may render it necessary to wear the tube afterwards; but with time we may ameliorate or even cure this unfavourable condition, and in any case life with a tube would be preferred to death.

Although iodide of potassium has been spoken of above as the constitutional remedy for syphilis, I am desirous of once more mentioning the success I have obtained with other salts of the metalloid. Manifestly it is not the potash which cures syphilis, and it seemed to me probable that the sodic salt would prove more easily assimilable. On trial I found it frequently could be taken by those who could not bear the potassic salt. The dose is about the same. Indeed, weight for weight, it has more iodine than the commonly used compound, and yet can be more easily taken. I am therefore desirous it should meet with a more extensive trial. I believe my experience is supported by that of Professor Sigmund.

I also find the iodide of calcium to be an excellent preparation, easily borne, and more agreeable to take. It may, in fact, as my patients know, be taken as a substitute for table salt. It is really desirable for all to know that the salts of iodine are not all so unpalatable as the one in common use. For the specimen of this salt, which I exhibited last year to the Medical Society of London, I am indebted to Mr. Tichborne, a gentleman whose devotion to science and readiness to place his great chemical and pharmaceutical knowledge at the service of the Profession is well known to the readers of this Journal.

Iodide of ammonium has also been proposed as a substitute for the ordinary salt, and in some cases will be found a most useful preparation.

Lastly, I may mention Iodoform. This remedy possesses important properties, and its local action may be taken advantage of in several of the forms of disease to which allusion has been made.

There are many other points to which attention might be directed in a lengthy paper.

In this brief outline, I have only attempted to give a sketch of those forms of the disease which are constantly under my observation, and of the treatment I have found most effectual.

ENURESIS:

ITS CAUSES AND TREATMENT.

A CLINICAL LECTURE DELIVERED AT THE LONDON HOSPITAL

By Dr. Bathurst Woodman,
Assistant-Physician to the London Hospital, and Physician to the North Eastern Hospital for Children.

The subject of our lecture to-day is not itself a disease; it is a symptom dependent upon a number of causes, some of which are met with in one case, and some in another. It is more commonly known under the name of *incontinence of urine*, and may of course occur by day as well by night; but as the latter form is more commonly met with you will find that most of the cases brought to you come with the history that "they wet the bed at night." The majority of the patients are young, and I am perhaps not wrong in saying that this affection is most common from the age of three or four up to fourteen or sixteen years. It is not easy to say how soon a young infant acquires the power of retention, since part is due to health, part to instinct, and part to education. But in general, we find that it is early acquired by children of average intellect. There is a common notion prevalent, that this affection is due to laziness or dirtiness, or some other assumed moral delinquency on the part of the young patient. In consequence of this belief, children are often punished severely, and usually without the slightest benefit; although undoubtedly there are cases in which this harsh treatment has proved effectual. I will not deny that very bad-tempered, or exceedingly lazy children may be capable of voluntarily defiling the bed-linen, either to annoy their parents or attendants or to save themselves trouble, but such cases are exceedingly rare; and perhaps even these are to be put down to a certain mental deficiency, such as often exists in cases of moral insanity.

I make no apology for introducing this somewhat unsavoury subject to your notice, because to those who rightly estimate their professional duties, there is "nothing common nor unclean." But if it were necessary to appeal to lower motives, I might tell you that there are few cases met with in practice which, when rightly treated, bring more credit to the medical attendant than these cases of enuresis, partly I believe because the subject is either passed over so slightly, or treated so unscientifically, in most of our text-books of medicine. The surgeon just mentions it, and leaves it to the physician. The physician alludes to it, and refers it back to the surgeon. I mean in our hand-books. What I know about it, and what I have to tell you I have had, for the most part, to find out for myself, often by the painful stimulus of failure in my attempts to cure. In so saying, I do not claim any original discoveries, or to be in the slightest in advance of my teachers, or of the medical authors of the day. The facts and the principles I shall lay before you are no doubt all to be found in print, as they are in Nature, but they lie scattered here and there, wide apart, and are not easy to refer to when such a case occurs to you in practice, and the subject is often scarcely alluded to in systematic lectures. Nor do I apologise for dwelling in some detail on a mere symptom, because this particular symptom is so disgusting, that it disqualifies a boy from almost all our public schools, and many private ones, and is in both sexes, if it be long continued, a bar to matrimony, as well as a loathsome hindrance to the enjoyment of social intercourse. Before introducing the cases on which I found these remarks to your notice, I want to impress strongly on your minds, three or four general principles.

1st.—I assert, without fear of contradiction from any one who has really studied the subject, that nine out of ten of these cases are *not the result of paralysis of the bladder, nor even of disease of the bladder at all, but that they are the result of reflex action.* I need not remind you that a reflex action is one done without reflection, but I may tell you in confirmation of this, that in most of these cases of enuresis, the bed is wet whilst the child is asleep.

2nd.—I must strongly insist upon the fact that the exciting causes of this reflex action of the bladder and the muscles which lead to the extrusion of urine are many and diverse. It naturally follows that a successful treatment must be based either upon a lucky accident, or upon a careful investigation of the causes, and an appropriate medication or treatment which shall remove or obviate them. And it follows almost as naturally that the scientific treatment of such cases will impress into its service all the aids that practical chemistry, the microscope, or the test-tube, or any other scientific instruments, and modes of research can afford us, and that in future years we shall hear no more of proposals to give the syrup of iodide of iron in all cases as a specific for enuresis, or of congratulation upon the *success* of such treatment, after many *months* of such medication. After this somewhat long preface let us take the first case which presents itself to-day.

It happens to be a man of middle age—in fact, he is about 52—and he tells us that for the last six weeks he has been unable to control his bladder, particularly at night. In the day time he has constant desire to pass water, but is often unable to do so in time; at night it passes from him involuntarily. Further questions and examination of the *rectum*, show us that this man has malignant disease of the lower bowel, and that this is in a state of ulceration or breaking down. My surgical colleague has left early to-day, so I prescribe for him opiates taken by the mouth and administered per rectum, in the hope (afterwards verified) of relieving this symptom. We must not, of course, promise to cure such cases. They are most common in adults, but a fellow student of mine, the late Dr. Heckford, has put on record in the Obstetrical Society's *Transactions*, Vol. X., p. 224, a case where a female infant, æt. 10 months, was brought to him with incontinence of urine, found to depend upon villous, or medullary cancer of the vagina. There are other cases, although they are very rare. In general, we can only relieve, as when brought to us they are generally beyond the stage at which we could remove the growth with safety.

Our next case is a little girl, who is barely 3 years old. We inquire her history and learn that she has lately had an "ulcerated mouth," and that she wets the bed at night; the two affections are almost coeval. On examining her we find little sores (stomaceæ) probably herpetic, on her tongue, inside her cheeks and on the gums. Her mother denies that the privates are sore, but you can see for yourselves, that she is a very typical case of eczema pudendi. One of you has just suggested that this is due to the irritation of the urine, and is, therefore, probably not the cause. I do not agree with him, because analogy is against this view, and besides, I find here evidences that the eczema was herpetic in origin, as well as the sores of the mouth. We shall order her what has proved successful in numerous similar cases, the pharmacopœial glycerine of tannin, to be applied to the mouth and to the pudenda. She is to sit in a warm bath as much as possible, and to take a tonic, such as steel wine, or a little chlorate of potash and bark. I confidently predict for her a rapid recovery.

The third case is a boy, æt. 8 years. His mother tells us that the incontinence has existed ever since his birth. On examination we find him with an excessively tight prepuce; there is an accumulation of *smegma* (or that soapy, or cheesy-looking secretion which is poured out from the mucous glands of the corona and thereabouts in the male, and from the parts in the vicinity of the glans clitoridis in the female); and the meatus urinarius is excoriated. We hand him over to the surgeon for circumcision, with almost certainty of cure. Where parents refuse this desirable operation, much relief may be given by syringing warm soap and water, and afterwards olive or almond oil under the prepuce—and also by stretching the prepuce forcibly with forceps. One of you asks if he may not have *stone* in the bladder? Undoubtedly this is a not uncommon cause of enuresis—but the case wants some important symptoms. There is no prolapsis ani, no blood in the urine; the symptoms are almost congenital, and the child does not seem to suffer much. If, however, there were a reasonable doubt, the bladder should of course be sounded. I will now narrate to you some cases which have occurred either amongst the patients here, or at the Children's Hospital which I attend.

(*To be continued.*)

◆

XYLOL, THE NEW REMEDY FOR SMALL-POX.

By C. R. C. Tichborne, F.C.S., M.R.I.A.

Xylol, xylene, or ethyl-benzine as it has been respectively called, is one of a homologous series of hydrocarbons, of which the well-knowr benzine and toluene form the two first. These hydrocarbons are all formed from coal tar naphtha. Xylol was first procured by Hugo Müller, but its nitro-compound had previously been discovered by Warren De la Rue in 1856. Coal tar naphtha is submitted to fractional distillation until the part which boils at 141° is separated, this is submitted to the action of fuming sulphuric acid, which dissolves the xylol and leaves the other hydrocarbons. The xylol is then separated by distillation from this mixture.

Xylol is said to have been used by Dr. Zuelzer, the Senior Physician at the Charité Hospital at Berlin, with great success in cases of small-pox. The theory of its action would appear to be that xylol is taken up by the blood, and acts as a disinfectant. The vapour seems to the writer to possess faint, and not very well marked, anæsthetic properties—this may be due to the presence of a small quantity of benzol, or the other hydrocarbons. The antiseptic properties of this group of compounds are well known, and thus probably the specific action of this one. The boiling point is variously stated at 139° to 140°. The specimens examined by the writer, generally commenced to boil at about 135° C. The specific gravity was ·866.

It is said that the purity of xylol is of importance, but unfortunately there is no very ready method by which the ordinary practitioner might detect its purity. It should be soluble in fuming sulphuric acid, but it is not soluble in the ordinary sulphuric acid of the Pharmacopœia.

It has a faint odour something like benzol, and an aromatic taste. The doses is three to five drops for children; ten to fifteen drops for adults every hour to every three hours. It is quite harmless in reasonable doses. In Berlin it is given in capsules. As it is very insoluble the best method of giving it would be in an emulsion of almonds. When once assimilated it is rapidly oxidized in the body, this fact being demonstrated by the production of a peculiar odour in the urine, which, however is quite distinct from xylol itself.

BULLET WOUND OF THE BLADDER (*a*).

By Arthur Edward Barker, L.R.C.S.I.

The following case which I have taken from my German notes may perhaps prove of interest to the members of the Surgical Society, as illustrating what the bladder may suffer under certain circumstances, without any lasting or permanent injury. The case was observed in the Klinik of Dr. Busche, Surgeon-General in the late war, who attended the man, and whose last operation on him was performed in his Klinik in the beginning of November of the last year. Dr. Busche has most kindly permitted me to make any use of the cases occurring before us in his practice in two large hospitals, by publication or otherwise, a kindness of which I gladly avail myself, as the case appears to me instructive as well as highly interesting.

Peter S. (soldier). At the time a healthy young man of about twenty-four years of age was wounded in the battle of Bapaume, on the 3rd of January, 1871. Three balls had entered almost, if not quite, simultaneously in different parts of the right gluteal region. The two lowest openings were about three inches from one another, the third about an-inch-and-a-half above a line joining the two lower ones. Two of the balls had evidently left the body, and strange to say, by almost the same opening in the middle of the left groin, just over Poupart's ligament. The wounds showed that they had made their exit within half-an-inch of each other, causing in their course injuries to the bladder, for the urine flowed copiously through the openings in the groin. Whether the third had also passed through one of the openings was impossible to say, but it would indeed be an extraordinary coincidence if the three projectiles entering at such a distance from each other and probably in various directions, should have so converged as to nearly meet just when piercing. It is, however, possible. Of course nothing special could then be done, and he was simply placed on his side and attended to in the expectation of seeing the fearful effects of urinary infiltration setting in. This was far from being the case, however, and after the urine had been for some time flowing off solely through the openings in the groin, it began to come *perurethram* and the wounds in the inguinal region healed with the several others in a most healthy manner. The patient then left the Lazaret apparently quite well, but after a considerable space of time complained of difficulty in passing water. On search being made with a sound, a hard body was discovered far back in the urethra. It was carefully grasped with a fine forceps and extracted, proving on examination to be a splinter of bone (probably from the os ilium), about half-an-inch long, and in one part about a quarter of an inch broad. Fortunately it lay in such a position as allowed of its easy removal. In this manner within a short space of time four similar splinters were extracted, each time relieving the difficulty in passing water, and the man enjoyed a period of rest. After a while, however, he began to complain again, and this time of pain in the glans penis, with the other symptoms of calculus; the urine being much altered. On sounding, a tolerably large stone was discovered, apparently of soft consistence, and it now became a question of importance, as well as great interest. Might not the third bullet be the nucleus of the calculus? The uncertainty and impossibility of determining this, and at the same time the probability of its being the case, pointed, of course, to the extraction through the perinæum in preference to lithotrity. As the man's health was already suffering from the distress and bad state of the bladder and urine, it was at once undertaken (Nov. 8th 1871) in the usual manner; but owing to the softness of the stone, and the necessity of grasping it with a small forceps, on account of the prostate being unusually small, the former broke very frequently and slipped, occasioning much delay, the extraction lasting more than half-an-hour. It was finally removed, however, and the detritus washed out with the irrigator. Then that simple after-treatment which is always had recourse to here in such cases, and which seems to have so much to recommend its wider adoption, was resorted to, namely :—The cut in the perinæum washed clean by the stream of water from the irrigator, was allowed to close completely, the legs being brought together, a pledget of charpie moistened in solution of carbolic acid was alone laid over the surface, no catheter or anything else being left in the wound. The patient was then put to bed, lying on his back with his legs flexed on the body and knees flexed over a high pillow, the latter being kept well together, the orders being that whenever he felt the slightest desire to make water he should be helped, in the same position, into a warm bath, and there allow the urine to pass quietly through the opening. The advantages of this method seem so evident, and in all cases were followed by such good results, that they are deserving of mention (if not already known). In this way is avoided the fever produced by the irritation liable to follow from the presence of the catheter in the bladder and wound, the sides of the latter lying together. On the slightest desire to empty the bladder the patient can easily be lifted into the warm sitz-bath, and there do so under water, which has several advantages, first the air cannot come in contact with either the wound or bladder; second, the urine on entering the cut is immediately deprived of its irritating properties, by being diluted and at once washed away, the wound being closed clean by bringing the legs together again. In the same position he is lifted again into bed, the bladder empty, the wound, without having been touched, cleansed from all the pus and urine and closed from the air. Near the bed of a patient so treated one never perceives the ammoniacal odour which by those managed in the usual way is commonly present (in spite of the utmost care), owing to the trickling out of the urine and wetting of the bed-clothes. The only dressing required is a pledget of wet lint. The warm bath moreover, is in itself most beneficial. With this patient things seemed to go wonderfully well, after a few days the water began to come partially through the urethra, and shortly after ceased to come by the wounds, the latter healing rapidly and cleanly. The condition of the bladder also improved very quickly, and the urine soon became normal, so that in a very short time he would be called almost quite well, when he was attacked with an acute epididymitis on the right side. Under ordinary treatment, however, this too passed away in a few days, and the patient left in good health for his home. The calculus was of the ordinary soft phosphatic composition, and did not contain the bullet as a nucleus.

◆

CASE OF LATERAL LITHOTOMY (*a*).

By Henry G. Croly, F.R.C.S.,

Surgeon to the City of Dublin Hospital.

The patient, from whom the calculus which he now exhibited had been removed by the lateral operation, was a man thirty-five years of age. He was admitted to the City of Dublin Hospital on the 13th of July last, having been sent there by Dr. Bagot, of Enniskillen. The following brief history of the case had been taken by the resident pupil :—

"The man had been suffering for fifteen years, and was treated in some remote part of the country for stricture. He did not complain at any time of the ordinary symptoms of stone, but had a difficulty in passing water. The first symptom that attracted attention was the gradual lessening of the stream and the high colour of the urine. On the 20th of December, 1871, he felt, when jumping across a ditch, as if something suddenly fell into the bladder, and he experienced considerable pain in the perineum. He observed also that his

---

(*a*) Read before the Surgical Society of Ireland.

water was tinged with blood. Shortly after this he was sounded by Dr. Bagot, and a stone detected. On the patient's admission to the City of Dublin Hospital, there was found a very large deposit of pus in the urine, and a considerable quantity of blood. He complained of a weight in the perineum, and was extremely nervous; there was great difficulty in sounding him. However, having placed the patient under chloroform, and having introduced the sound, it came into contact with the stone. On the 1st of August, he (Mr. Croly) performed the ordinary lateral operation, and his reason for determining on that operation instead of attempting to crush the stone, was that the man was of an extremely nervous temperament, and bore the introduction of the instrument very badly; that he had suffered from rigors on the introduction of the instrument, and that the bladder was in a very irritable condition. By seizing the stone in the lithotrite he could form a good idea of the size of the stone; he found he could not move it about freely in the bladder, and he therefore came to the conclusion that it was partly encysted. There was extreme difficulty experienced in getting the man under the influence of chloroform, it being fully an hour before he could be brought perfectly under its influence. The operation was performed with a staff grooved at the side, and one knife. On introducing the finger into the bladder, the larger portion of the stone came out in the forceps, and finding it seemed smooth at one point he concluded there was another portion of the stone remaining in the bladder. On examining further, he found the flattened portion of the calculus was encysted, and he removed it with a scoop. The bladder was then carefully washed out. The chemisette canula was introduced into the bladder and nothing unusual occurred until the third day, when the chemisette canula was removed at 2 p.m., and at 6 o'clock, he (Mr. Croly) received a note from the resident pupil to say that the man had not passed any water, and that he had very severe rigors. He found that the man had passed no urine, and that none was coming through the canula into which a little tepid water was injected on the supposition that it might have got accidentally stopped. The patient was placed in a warm bath, and he was only a short time in it when he passed water freely, and for several days afterwards he could not pass water until he was placed in a warm hip-bath. The wound gradually closed and the case terminated favourably. On the 21st of October he had a letter from him saying that he had got on very well and was improving every day, and that on going to show himself to Dr. Bagot, the doctor did not at first recognise him he was so much improved. Had he (Mr. Croly) attempted to crush the stone he had little doubt that the smaller portion would have been left in the pouch behind the prostate to form the nucleus of another stone, and the cutting operation was therefore the proper one. With regard to the introduction of the canula, each time that he operated for stone he introduced the chemisette canula. The first time it acted as a foreign body and no urine came, and it had to be removed. In the next case it acted admirably, as it also did in the present instance. With regard to the occurrence of rigors, which was a point of great interest in the case, he asked himself was it possible that they might have been caused by the urine getting round the neck of the bladder? He did not think, however, that this could have been the cause, for he had made only a very small opening in the neck of the bladder. It was very important that the opening should be just sufficient to allow the finger, the gorget, and forceps to get in. Mr. Colles, of the Indian Army, who had cut in ninety persons for stone, told him that whenever the opening made in the neck of the bladder was large the patient died, and whenever it was such as to admit only the finger, so that the sphincter of the bladder grasped the finger, the cases terminated favourably.

◆

Hospital Reports.

ST. GEORGE'S HOSPITAL.

The following miscellaneous cases have lately been under Dr. Ogle's care:—

A woman, admitted with swelled face from cold, and suffering from alcoholism, was found, on recovery, to be unable to open both eyes to more than half their proper extent. In addition to this partial *ptosis*, there was paralysis of the *muscles* of the *eyeballs* which were almost completely fixed, their axes being tolerably parallel. The pupils were equal and of actual size, acting fairly to light. Sight was on the whole very good, and objects could be seen though placed very far to either side of the head. She stated that this condition of the eyes had existed for seven years, but could assign no cause.

A woman, æt. 68, a midwife, who had continued to menstruate until she was past 52 years of age. She had suffered from constitutional syphilis, which she had acquired in the hand whilst engaged in the practice of midwifery.

A man with disease of the heart, who had had a cut over the left eyebrow, leaving a scar, which, owing to injury of the supra-orbital branch of the fifth nerve, had produced loss of power to a considerable extent of the occipiti-frontalis and orbicularie muscles.

A woman transferred to Dr. Ogle by Mr. Carter, with anasarca and albuminuria, which had apparently resulted from *pregnancy*, and in whom Mr. Carter had found by the ophthalmoscope, much albuminous deposit in the fundus of the eye. The eye is much improving, and the albumen quickly diminishing in the urine under the use of steel. At the time of this note, it is three months since her confinement.

◆

Transactions of Societies.

SURGICAL SOCIETY OF IRELAND.

FEBRUARY 2ND, 1872.

Mr. WHARTON, President of the Royal College of Surgeons, in the Chair.

THE Society met at the College of Surgeons.

DR. RICHARDSON (Hon. Sec.) read a paper from Dr. Arthur Barker, detailing the facts of

A GUN-SHOT WOUND OF THE BLADDER, FROM WHICH THERE HAD BEEN PERFECT RECOVERY,

which will be found at page 184.

DR. TUFNELL said the Society was indebted to Dr. Barker for the interesting case he had communicated. The only observation he had to make on the case was, that he thought in all probability the bladder was very full at the time of the occurrence, and the peritoneum was thus lifted out of the way. A few years ago, in Ireland, a man was shot through the rectum, and the ball escaped over the pubis. The urine was discharged freely through the rectum, and the man recovered without a bad symptom. In that case he had not made water for a long time previous to receiving the wound, and the bladder was very full.

DR. FLEMING said that cases of injury to the bladder from gun-shot wounds had occurred in Ireland as well as elsewhere, and in many of these the termination was not fatal, though he would not say they terminated so favourably as the case described by Dr. Barker. It would be in the recollection of some members of the Society that the son of the late celebrated Dr. Cheyne, during one of the disturbances in the country received a gun-shot wound, and on two or three occasions was operated on with a view to the removal of the bullet from the bladder. The last operation, which he (Dr. Fleming) witnessed, was performed by the late Mr. Cusack in Stevens' Hospital, and on that occasion the bullet was found to be embedded in a portion of the pelvis. The bone was removed, and the recovery of the young gentleman was perfect. There were a great many cases on record of these gun-shot wounds of the bladder and of other cases where the bladder had been most seriously involved in fractures of the pelvis. Dr. Jameson reminded him of a case where the ball passed through the bladder, and yet the man lived for two or three years after the occurrence of the accident. The man was afterwards hanged, and he (Dr. Fleming) made the *post mortem* examination.

Mr. H. G. Croly brought under the notice of the Society

A CASE OF LITHOTOMY,

which will be found at page 184.

The **President** observed that in the case described by Mr. Barker the patient was always put into a bath when he wanted to make water; and in Mr. Croly's case it was found when there was a stoppage of urine, the taking out the canula and putting the patient into a warm bath, gave him relief.

Dr. Denham said there was one point of interest in the case, namely, the smallness of the wound made in the bladder; with reference to which he wished to make a remark. When he was a student in Edinburgh he saw the late Mr. Liston operate very frequently. He was remarkable for his success in all cases and principally in lithotomy; and he always mentioned as one of the causes of success, the making of a small opening into the bladder. He had long fingers; and he said that the moment the urine came he passed the index finger into the wound and enlarged it with his finger and thumb until it was sufficient to admit of the extraction of the stone.

Dr. H. Kennedy said that with the surgery of the case he had nothing to do. But there was a point which seemed to him one of very great consequence,—he meant the diagnosis of stone in the bladder. He had both heard and read of cases where the greatest doubts and differences of opinion existed, and it was even on record that cases had been operated on and yet no stone was found. These obscure cases chiefly occurred in children. It would be in the recollection of some of the members that several years since, the late Dr. Bellingham stated to the Society a case where the difference of opinion was very great, some asserted that a stone existed, and others not. Yet under medical treatment all the symptoms disappeared and the child remained well for a period, if he recollected right, of upwards of two years; at the end of which time all the signs returned, and the operation for stone was successfully performed. As bearing on this point, he might mention that he had read lately of a case occurring in London, where a stone of only eight grains in weight was extracted. It was easy to see how so small a stone might give rise to great diversity of opinion. But besides this source of difficulty he had come to the conclusion that the symptoms of stone might exist for years and yet no stone be present. On no other supposition was it easy to explain the case given by Dr. Croly, where the signs of stone were present for fifteen years, and during part of this period been mistaken for stricture. About seven months since, he had seen a case where, except by sounding, all the usual symptoms of stone were present. The patient was a boy of eight years of age; yet in the course of three weeks, and by medical treatment alone, all the signs disappeared and the boy still remains perfectly well. He considered the question of diagnosis one of considerable moment. As to what had fallen from the President about the use of the warm bath, it seemed easy to explain its effects for it was known to be a powerful agent, whereas cold or even the presence of a stranger could, and often did, prevent a patient from passing water.

Dr. Benson said that a year and a-half ago, he called in Dr. Croly to see a child who had symptoms of stone, and he was so satisfied the symptoms were worth investigation that he sounded and could detect nothing of the kind. He put the child under medical treatment, and there had been no symptom of calculus since.

Mr. L'Estrange observed that there were very few cases of stone in the bladder that could not be detected by the sound, which he had invented, and the size of the stone ascertained. The late Sir Philip Crampton had a case in which he brought out the stone between the nail and his finger; and if there had been a sound then used it could have been observed. Mr. Croly said the stone was encysted; but he (Mr. L'Estrange) did not think that an objection to lithotrity; for Mr. Lysaght, of Roscommon, performed that operation with his (Mr. L'Estrange's) instruments, and though he was able to say it was sacculated, he brought out the stone.

Dr. Fleming remembered Sir Philip Crampton operating in private for stone in a child, Mr. Colles and Mr. Cusack both being present, and the stone could not be found. Sir Philip was much distressed when he was obliged to state to the father of the child that he could not find the stone; but when washing his hands he saw a clot of blood on the sleeve of his coat, and in it was found a very minute calculus. Caius operated for stone in one instance but could not find it, and his assistant when washing the forceps after the operation discovered in it a small stone. There was a large amount of interest connected with symptoms of stone in the bladder where none existed and where the symptoms arose from some malformation of the prepuce, or urethra, or from some condition of the urine itself, as when it was loaded with uric, or oxalic acid. Set the urine right and the symptoms disappear.

Mr. Croly, in reply, said it was not his intention to discuss the subject of diagnosis. Cases of congenital phimosis, or worms causing symptoms simulating those of stone, were well known to every practitioner, and they generally sounded ten times for once that they succeeded in detecting stone in the bladder of a child. He would suggest to Dr. Kennedy that in the next case he met with he should get the child sounded instead of putting it under medical treatment, for it would be an injury to the child to keep it under such treatment for months if a stone really existed which could be removed at once by operation. Mr. L'Estrange's instruments were excellent, and he (Mr. Croly) used them. In this case, however, there was no difficulty in detecting the stone,—the moment the sound was put in it struck the calculus, and the other symptoms showed that it was encysted. In such a case where the stone was so soft that a portion of it came away after the operation, the other portion remaining embedded in the little pouch, he thought if the crushing operation had been resorted to there would have been danger of leaving a portion of the stone behind; but what guided him most in selecting lithotomy was the man having a very irritable urethra and a diseased condition of bladder, which he thought unfavourable to the operation of lithotrity,

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, FEBRUARY 28, 1872.

UNIFORMITY OF QUALIFICATION.

We are requested by Dr. Gairdner of Glasgow, and Dr. Sanders of Edinburgh, to publish a memorial respecting the recent proceedings on the part of the Universities and Corporations in Scotland, with a view to the formation of a Conjoint Board of Examination at the instance of the Medical Council, and which indicates the dissent of the memorialists from these proceedings on several grounds. We need not say that anything coming from Drs. Gairdner and Sanders receives our most respectful consideration, and the interest we have always attached to all questions of medical reform further prompts us to give prominence to whatever may influence its progress, even though we may feel bound to point out how much we disagree with it. Let us then look at this memorial. It says :—

> 1. The reason alleged for such proceedings in the first instance, viz., the attainment of "Uniformity of qualification," *i.e.*, a fixed minimum of medical knowledge and skill on the part of candidates, secured through examinations conducted upon a precisely similar plan by examiners making precisely similar requirements, appears to the undersigned an object neither desirable nor attainable.
>
> 2. Even were the object in question a desirable one, it evidently cannot be secured by the measures proposed. It is inconceivable that one Board sitting in England, another in Scotland, and a third in Ireland, each Board being of very complex constitution, and holding examinations in different places, without any concert or intercommunication, could possibly secure "uniformity" in any real sense of the word.
>
> 3. The immense number of candidates which would have to be examined in each division of the kingdom by the Conjoint Boards, would make it absolutely necessary either greatly to enlarge the number of examiners and to subdivide them into companies (of course with a still further loss of "uniformity" as regards results), or to work one set of examiners continuously day after day for long periods, with the practical effect of reducing their operations to a wearisome routine, incompatible with other professional pursuits on the part of the examiners, and entailing great hardship upon candidates by want of accommodation with the sessional arrangements of the principal medical schools.
>
> 4. The expense of examinations so conducted would be, if thrown upon the candidates, a very serious addition to the cost of medical education and qualification, without any commensurate results as regards the security of the public.
>
> 5. The undersigned are decidedly of opinion that if, for the public security, an additional examination requires to be introduced over and above the nineteen at present in operation, the cost of such additional examination should in any case not be thrown upon the candidates, nor yet on the existing examining bodies, but should be defrayed by the State, as representing the public.
>
> 6. The true object to be aimed at, whether in view of the public interest or that of the medical profession, is (in the opinion of the undersigned) *not* uniformity, nor yet a fixed minimum of qualification, but the watching and stimulating the existing examining boards through a systematic inspection, conducted under the auspices either of Government or of the Medical Council.
>
> 7. The undersigned profess themselves willing and anxious to facilitate to the utmost a thoroughly efficient system of examination in the Universities and Corporations with which they are severally connected, and would gladly welcome the visits of any Inspectors appointed on the part of the public to secure, as far as may be, efficiency on the part of all such examining bodies in the performance of their important duties. In the case of the Universities, such a system of inspection would be quite in accordance with the system already introduced by the Universities Act of Non-Professorial Examiners. The undersigned are thoroughly satisfied with this system, and believe that an extension of it would do good.
>
> 8. The details of such inspection should, in the opinion of the undersigned, be arranged between the State, as representing the public, and the Medical Council as representing the Medical profession.
>
> 9. The undersigned desire it to be understood that so far from objecting to a "Conjoint" system of examination, they would cordially welcome any voluntary joint action of different boards with the view of diminishing the labour and responsibility of examination, and the expense and trouble of it to the candidates. The objection that they entertain to the proposed system is, that it would not diminish either the expense or the trouble to the candidates, but would, on the contrary, increase both ; while, by removing the responsibility of the practical part of the examination in some measure from the existing Boards, it would tend very much to reduce all medical examinations to a low dead level, and would render it nearly impossible to improve them in accordance with the demands of advancing medical knowledge.

As in many other cases, we find in this memorial a good deal to commend, and as much or more from which we dissent. It is, for instance, at this time of day almost too late to be told that uniformity of qualification is not desirable. Perhaps those interested in their fear of dull uniformity and a single minimum embracing a knowledge of all branches of the profession imagine that the advocates of the one-portal system are all actuated by a desire to destroy all existing institutions. But no considerable party has any desire whatever to abolish or injure the Universities or Colleges. What is really desired is to take away the reproach of a system of competition downwards.

We admit the force of Clause 2. We have many a time pointed out that the establishment of three boards cannot create uniformity. But it is a step in advance in some sense. If England and Ireland agree to some practicable plan of this kind, it would be, we think, very unwise for Scotland to decline to do the same. The Scotch Colleges set the good example of combination and a single conjoint board, for that kingdom is only going a step farther in the direction in which our Scottish friends led the way.

With regard to Clause 3, it seems to us that it could not be more difficult for Scotland than for the other kingdoms which have determined to try.

With regard to cost, we look upon it as most easy to arrange.

As to this question of inspection, no doubt it might do good if the State were to employ independent men to carry it out. But will the country consent to pay them, when all the good they could do might be accomplished in a more simple and less costly way ? For the several bodies to watch each other as now done by the Medical Council is a solemn farce.

If a real one-portal system could be obtained, it would suffice to secure all the Universities and Colleges to their own management, only compelling them to withhold their diplomas from those who had not obtained the single license.

The last clause seems to us half an admission that conjoint action may, after all, be desirable. We, too, think voluntary amalgamation would be able to supersede compulsion, and only should rejoice to see an honest effort to carry it out everywhere. But human nature is imperfect ; and out of nineteen "authorities" it is scarcely surprising that some should be reluctant to put aside self and work for the good of the profession alone. We are glad to see Dr. Gairdner at last speak on Medical Reform ; and now that he has done so, we sincerely hope he will not again dismiss the subject. We have little doubt that in time, if he attended to the subject, he would become a supporter of our views.

DIAGNOSIS OF SYPHILIS BY THE MICROSCOPIC EXAMINATION OF THE BLOOD.

We have already given some account of the alleged discovery of Dr. Lostorfer, and next week shall issue a fuller account of the subsequent meetings, when it was ably maintained, as already reported by us, that the so-called syphilitic corpuscles have no existence, or are only appearances to be found in healthy blood.

We do not propose here to enter into the controversy ; but before it has advanced further, we are anxious to place before our readers the effect produced by Dr. Lostorfer's communication on one present at the meeting. To effect this, we take the following letter from the *Boston Medical* *and Surgical Journal*, which, at the same time, shows how our American contemporaries keep pace with what is passing in Europe :—

VIENNA, January 12, 1872.

MESSRS. EDITORS,—I have just returned from a meeting of the "Gesellschaft der Aerzte," at which was announced a discovery of the most stupendous importance. I am eager to be the first to herald to the New World, through your pages, the greatest success—I may venture to say—as yet achieved by the microscope, to wit, the certain diagnosis of syphilis. I will give briefly, from memory, the course of procedure which led to this grand result, having first recorded the name of the propounder of the new theory as Dr. Lostorfer. Wishing to make a series of examinations of blood from syphilitic patients, Dr. L. applied to Prof. Zeisal in August last, who at once placed his wards at the service of the investigator. The manner of conducting the researches consisted in taking a drop of blood, placing it immediately between a slide and covering glass, then setting the specimen under cover. A large number of slides were thus prepared, and daily examined microscopically with a No. 10 immersion lens, Hartnack. The first two days nothing abnormal presented itself; but, on the third, minute shining bodies were discerned, which grew from day to day, until they attained the size of red corpuscles. The shape was, in most instances, round, but modifications of that form were here and there noticed; they were all, however, provided with tapering processes, or "sprouts." The number of these corpuscles to be seen at one time within the field of the microscope was variable, amounting in only one specimen to fifty. A month later these objects were still visible. A solution of sugar, as well as several other solutions, caused them to shrivel up, become, as it were, folded upon themselves, lose their shining aspect, and cease to grow. Cold was also found to affect their development, inasmuch as a temperature below 10° Reaumur (54° Fahr.) put a stop to all growth.

To prove the connection between these bodies and syphilis very many experiments were made with healthy and diseased blood, and the diagnosis confirmed beyond the possibility of doubt.

Blood was then daily examined while the patients were undergoing treatment with mercury (einreibungen), and after a certain time (in one case twenty-five days), during which the number of corpuscles was steadily decreasing, they had wholly vanished from the field. After these experiments, Dr. Lostorfer submitted himself to Prof. Stricker, and, later, to Prof. Hebra, to have his power of diagnosticating syphilis, by the microscopic appearances of the blood, put to the test. On various occasions he received from them numbered slides, with blood of syphilitic and non-syphilitic individuals. To their astonishment, he unerringly selected from the preparations those where the blood was tainted with syphilis, with the exception that on certain slides the blood was pronounced to be in a condition allowing of no conclusion being arrived at.

The discoverer gives the name of syphilitic corpuscles to these bodies, which he said must originate in one of two ways,—either from germs always present in the blood, but stimulated to growth by the syphilitic virus alone, or from such introduced bodily into the blood at the time of infection.

In conclusion, he read the records of a number of cases with his microscopic observations of the blood from day to day. As Dr. Lostorfer ceased speaking, a burst of genuine enthusiasm escaped from the assembled physicians, while Prof. Skoda rose to greet the hero of the evening as the proclaimer of what was destined to prove one of the most important discoveries of the age. He regretted that it was not customary in Austria to give medals or other rewards of merit in such cases, stating that, had this statement been made in Paris, he would have been crowned, as he deserved.

Prof. Stricker detailed the precautions taken to avoid error or deception in each of the trials to which Dr. L. was subjected. The latter's selection of diseased blood was always correct and decided, except in the few ruined specimens. To ensure the purity of the healthy blood, he had taken his own and that of his servant. After a while Dr. L. distinguished between these two, inasmuch as the Professor's was thicker and "dirtier."

Prof. Hebra had confirmed all that had gone before, and said he had been so much struck with the discovery that Prof. Stricker's blood "contained more filth (schweinerei) than that of any other living man," that he had instituted researches for similar peculiarities among his patients, but, thus far, without result. No words are needed to show the immense field for research thus suddenly thrown open to investigators, nor can the practical results likely to proceed from this study be over estimated. Microscopes all over the world will now be turned toward these new constellations, and every freak recorded.

Theories of unity and duality will soon cease to vex the earnest student and practitioner, and half of the skill and learning of dermatologists is made of no value by this simple and certain indication of the presence of the syphilitic virus. The testimony of two such renowned and incredulous men as Professors Stricker and Hebra is a convincing proof that these corpuscles are not bubbles to be pricked by the next impertinent microscopist. I trust I have not omitted nor misstated any of the main points of Dr. Lostorfer's paper, but if so, will send you in expiation of my offence a copy of his article as soon as printed.

I am, yours, &c.,
JAMES CHADWICK, M.D.

◆

THE CONJOINT EXAMINING SCHEME FOR IRELAND.

THE anticipation which we have expressed that the scheme for a Conjoint Examination as agreed to by the Conference of Licensing Bodies would be neither acceptable nor practicable has, we understand, been verified by the reception which it has met by the Governing Councils of those bodies to which it has been submitted. We believe it is true that both the Council of the Royal College of Surgeons and the Senate of the Queen's University have expressed opinions on it which amount to its rejection by them. The Council of the College of Surgeons, we understand, has dissented from those clauses which enable a student to pass the Conjoint Examination *before* he takes any qualification or pays any substantial fee. The Senate of the Queen's University, we are informed, have decided not to bind themselves to any scheme from which any of the co-operating bodies might withdraw at any time, but to await legislation.

The Apothecaries' Company have agreed to the scheme, and the University of Dublin and the College of Physicians have not yet decided upon it.

We conceive that this statement of the attitude of the licensing bodies hardly justifies the jubilation of the *British Medical Journal*, which considers that the Conference has reported "in an able and satisfactory manner."

That journal is of opinion that "to a competition which will lower the price of diplomas without injuring their scientific value the Profession cannot object,"—a view from which we dissent *toto cœlo*.

Whether we speak on behalf of the Profession, or the licensing bodies, or the public, we believe we are justified in saying that the admission of a flood of undiplomated four guinea doctors is neither prudent nor desirable.

We are informed by the same journal that the Irish scheme "corresponds with that planned and adopted by the English bodies." As a matter of fact, it is perfectly and essentially different in all important respects.

It is a subject for regret that the incompatibility of University and College interests in Ireland (where, unlike England, an active competition for Medical licensing exists between such bodies) makes a fair and broad arrangement for Conjoint examinations impossible. We had hoped for a better result; but we believe we can now look to Government for a far more equitable adjustment than the Irish Conference has offered.

SCOTLAND.

SIR ROBERT CHRISTISON, BART.

We defer until next week giving an account of the celebration of Sir Robert Christison's fiftieth year as a professor in the University of Edinburgh. It was in every respect a great success, and worthy of the occasion.

Notes on Current Topics.

Ligature of the External Iliac Artery High Up at Sir Patrick Dun's Hospital, Dublin.

We noticed in our number of January 17th that Mr. Butcher, in the operating theatre of Sir P. Dun's Hospital, ligatured the external iliac artery on the right side, high up, for a large inguinal aneurism, extending above Poupart's ligament, the patient being a man, æt. 68. We are happy to follow up the case, and state now that on the thirteenth day of this month, and the thirty-fifth after the operation, the ligature came away, not a trace of blood following it. The wound now is nearly healed, and the temperature and sensibility of the limb are restored to their normal condition, the same as the sound one. The aneurismal tumour is reduced to about the size of a section of half a billiard ball, and is quite firm and hard; all the circumference of the tumour has been rapidly absorbed, and we have only to add that the successful result of this serious case is most encouraging to operative surgery. Mr. Butcher has added in this operation one more success to the series which has obtained for him the character of being one of the most intrepid and skilful surgeons in Ireland.

The Medical Society of London.

The Treasurer has just issued his financial statement for the year, to the 31st January, ult.

The banker's book shows a balance in favour of the Society amounting to the sum of £262 16s. 7d., with the Society free of debt, and on the eve of having its funds augmented to the extent of the greater part of the revenue for the present year, through the falling due of its annual subscriptions. Financially, therefore, the Society is in a more flourishing condition than it has been at a corresponding date for many years past, if not for any year during the period it has been in existence.

The Treasurer also reports that it is very probable that, ere long, considerable expense will have to be incurred in consequence of the approaching termination of the lease of the premises, it will be greatly to the advantage of the Society if the exceptional outlay on this account can be met without its being necessary to make any exaction on the Fellows in excess of the ordinary annual contribution; and it is encouraging to be told that the Treasurer is strongly of opinion that this object can be realised if the same path of rigid economy be followed for a time that has been pursued during the past year, and indeed in bygone years, whenever like exigencies have occurred to render it necessary; and that without intrenching in any respect on the requirements of the Fellows, or the interests of the Society at large.

A general meeting will be held on the 4th March to receive the report, and elect the officers for the ensuing year. On the 8th March the dinner will take place, Dr. Andrew Clark in the chair.

Charing Cross Hospital—Report of the Registrar for 1871.

The Registrar of Charing-cross Hospital, Dr. Poer, has invented a valuable tabulated report of the cases treated in this hospital and which, if it were made a basis or model for other institutions, might become a valuable series of reference tables.

The total number of patients admitted to Charing-cross Hospital during the year 1871 was 1,402. Of these 678 were admitted under the care of the physicians, and 724 under the care of the surgeons.

Of the 1,402 patients 1,139 were discharged as cured or relieved, 143 died and 120 remained under treatment in the hospital on the 1st of January, 1872.

The average time which each patient spent in the hospital was (in round numbers) 32 days.

The number of days' nursing afforded by the hospital amounted (in round numbers) to 45,260.

The daily average number of patients in hospital was (in round numbers) 124.

This report is accompanied by seven tabulated statements:—

Nos. 1 and 2 show the various injuries and diseases for which the patients were admitted, giving the numbers of each sex and the result, *cure*, *relief*, or *death*.

No. 3 shows the cause of death with the length of stay in hospital of each fatal case.

No. 4 gives the result of every *post-mortem* examination during the six months ended December 31st, 1871.

No. 5 shows the cause, the nature, and the result of every operation performed during the six months ended December 31st, 1871.

No. 6 gives certain particulars respecting the cases of acute and subacute rheumatism admitted during the six months ended December 31st, 1871.

No. 7 gives certain particulars respecting the cases of acute febrile disease, other than rheumatism, admitted during the six months ended December 31st, 1871.

Private Practice by Naval Surgeons.

We learn from the *Malta Times* that the medical officer of one of Her Majesty's ships stationed on the Danube has been transferred to the East Indies, for the apparent cause that he was conducting a considerable private and dispensary practice, and receiving fees as a private practitioner which, as Surgeon in the Queen's Navy, he was not entitled to do. The removal of this gentleman is represented by the *Malta Times* in the light of a great grievance, but we take a diametrically opposite view and consider that it would be neither healthy for the service nor fair to civil practitioners that the medical officers of every ship which might be stationed at a foreign port should go into competition with the local physicians.

Female Medical Missionaries.

Several lady doctors have gone out to India from America in the steamer "Singapore," for the purpose of engaging in work as medical missionaries. The *Scotsman* says that one of the ladies now studying medicine in Edinburgh contemplates undertaking the same work if ever she and her companions are allowed to complete their studies, but that so far from furthering this end, the directors of the Medical Mission in Edinburgh have refused to allow the lady students even to attend in their Cowgate Dispensary.

Suppression of Drunkenness in France.

THE Committee of the French National Assembly which was directed to examine the Bills on this subject, have presented their report. They recognise the principle that a penal law for such a purpose is a legitimate mode of dealing with it and they consider that such an enactment is urgently required because drunkenness has become a social vice, shameful in the present and dangerous in the future. Having declared that the existing enactments are quite insufficient, the committee proposes a specific code of law founded on the remarkable work of M. Theophile Roussell.

Education of Dispensers in America.

ACCORDING to a recent report of the New York Commissioners of Pharmacy, 666 persons, out of over 900 candidates, have been licensed, out of these less than thirty succeeded in passing the examination at the first trial. The *Chemist and Druggist* says that egregious and discreditable failures in chemistry, pharmacy, and toxicology, as well as in "doctor's Latin," characterised the large majority who were turned back by the ordeal. Only three out of over 700 applicants could read the simplest Latin sentences: but more than this number were familiar with the jargon of the prescription counter. "To express the idea of 'the same,' the word *ejusdem* was used; and the Commissioners report the results of this test. One clerk, it is stated, replied that in no store where he had been employed had he ever seen or heard of "infusion of ejusdem." This famous prescription was presented at eighteen drug stores in the most populous part of Broadway, and in each the same answer as the above was returned.

Preservation of Food.

THE Food Committee of the Society of Arts has received for examination from Mr. C. Nielsen, of Copenhagen, specimens of an effort to solve the problem of fixing blood in forms suitable for food, and at the same time capable of preservation, viz., (1) as sausages, puddings, cakes (being mixed with fat, meal, sugar, salt, a few spices), to serve as a much cheaper compensation for meat, and intended more especially for the use of the poorer classes; (2) as blood-chocolate, more especially suitable to be used in hospitals and otherwise in medical practice, in which latter form it has been recommended by Professor Panum, at a meeting of physicians at Copenhagen, October 24th, 1871, and is now being employed at the hospitals of Copenhagen, the attention of physicians being directed to its effects.

In the *Allgem. Wien. Med. Zeitung*, of 6th of February, we notice the following:—"The emancipation of ladies desirous of learning makes propaganda even in Europe. At this moment twenty-four ladies, young and elderly, are attending the Polytechnic School at Zurich. Russia sends the strongest contingent." England will soon have the power of boasting that it is the only country where women cannot graduate in medicine, or indeed even *study* the art. We hear from Dr. C. R. Drysdale, that the Committee of the Farringdon General Dispensary, London, has just suspended him for a month from his functions as Senior Physician, because some of the Committee object to him allowing ladies to attend his clinique, although there are no male students at the dispensary.

Methylated Spirit in Tinctures.

FROM the supplement to the 14th Report of the Commissioners of her Majesty's Inland Revenue, recently issued, it appears that only one instance has occurred of the illegal use of methylated spirit in the preparation of tinctures, the substance so prepared being laudanum, which from its peculiar odour, affords great facilities for the utilisation of methylated spirit.

Health of Dublin.

IN the Dublin Registration District the births registered during the week ending 17th February, amounted to 145. The average number in the corresponding week of the years 1864 to 1871 inclusive was 178. The deaths registered during the week were 244. The average number in the corresponding week of the previous eight years was 184. 45 deaths from small-pox were registered during the week. In the North Union Small-pox Hospital three persons (City cases) died from small-pox. 12 deaths from small-pox were registered in Belfast, and 27 in Cork. 14 deaths were caused by fever, viz., five by typhus, three by typhoid, and six by simple continued fever. Scarlet fever, measles, and whooping-cough caused four deaths each. 10 children died from convulsions. 38 deaths resulted from bronchitis, and three from pneumonia. Six deaths were referred to paralysis, and one to apoplexy. Heart disease was the cause of nine deaths. One death was attributed to stone, two deaths were referred to kidney disease unspecified, and one to Bright's disease. Four deaths were referred to liver disease. 31 persons fell victims to phthisis, one to mesenteric disease, three to hydrocephalus, and two to scrofula. Cancer killed six persons. One person died from the effect of burns.

YEARLY SUMMARY.

Births.—During the year 1871 there were registered in the Dublin registration district 8,860 births, or 29 per 1,000 of the population. In London the number was 34 in every 1,000; in Glasgow 39 per 1,000, and in Edinburgh 34 per 1,000.

Deaths.—8,144 deaths were registered in the Dublin registration district during the year 1871, being equal to a ratio of 1 in 38, or 26 in every 1,000 of the population. The deaths in Belfast were 26 in every 1,000, in Cork 27 per 1,000, in Limerick 26, in Waterford 21, in Galway 22, in Sligo 18, and in Londonderry 20 in every 1,000 of the population. In London 25 in every 1,000, in Glasgow 33 per 1,000, and in Edinburgh 27 in every 1,000 of the estimated population.

Diseases.—The deaths from zymotic diseases registered during the year amounted to 1,720, affording a ratio of 1 in every 4·7 of all the deaths. The number of deaths from small-pox registered in the Dublin district during the year amounted to 207, or 1 in 39 of the total deaths. 34 deaths of City patients occurred in the North Union Hospital, situated without the Dublin registration district. 398 deaths, or 1 in every 20 of the total registered, were caused by fever, viz., 114 by typhus, 190 by typhoid or enteric, and 94 by simple continued fever. Scarlet fever caused 253 deaths, showing a decrease of 195 compared with 1870. 252 deaths were referred to diarrhœa, against 320 in the preceding year. Whooping-cough contributed 212 deaths. 95 deaths resulted from croup. 26 deaths were caused by measles. Diphtheria was the cause of 22 deaths, and quinsy of six. To convulsions 554 deaths were ascribed. 1,203 persons died from bronchitis, and 192 from pneumonia. Heart disease killed 303 persons, pericarditis 11, and aneurism 30. Phthisis or pulmonary consumption proved fatal in 977 instances, mesenteric disease in 128, hydrocephalus in 178, and scrofula in 62. Cancer caused 142 deaths. Apoplexy was the assigned cause of death in 127 cases, paralysis in 133, epilepsy in 32, and cephalitis in 60. 41 deaths were caused by Bright's disease, 71 by kidney disease unspecified, three by stone in the bladder, 132 by liver disease unspecified, 12 by jaundice, and 15 by hepatitis.

Vegetable Powder.

According to the *Mouvement Médical*, "vegetable powder" is for some purposes superior as an application to linseed meal. Unfortunately, the nature or composition of the preparation is not given, yet the following remarks regarding it may have an interest for some of our readers :

The powder in question is finely granulated and dark coloured, more so than linseed meal ; its odour reminds one of oleaginous grains ; its taste is sweetish. Applied to the tongue this powder gives a sensation of freshness, to which soon succeeds one lightly acrid. It is easily soluble in water, and when mixed with a little saliva immediately acquires a semi-mucilaginous consistence.

The last property shows the very hydrometric power of this powder, which we continue to call, for want of a better name, "vegetable powder ;" in fact, while being very finely granulated, it gives to the finger a sensation of the dryness which linseed meal leaves ; it absorbs a great quantity of water, and with a spoonful of this powder a poultice the size of one's two hands may be made ; this presents the appearance of very soft pulp, more equally mixed with water than that obtained from linseed meal, and preserving its humidity much longer.

Water is everything in a poultice. If it is more efficacious in this form than as a lotion, it is because the poultice has a certain weight, reduced certainly as much as possible, but much greater than that of a bandage steeped in fluid ; it is also kept in its place by a slight pressure ; these different actions cause the water to penetrate more closely into the tissues. The poultice is, so to speak, but a medium for the fluid ; of what use is it then when the water which it contained has completely evaporated ? The first condition, therefore, of a poultice is to preserve as long as possible the water employed in its preparation.

But it may be said that it is easy to make a linseed-meal poultice more hydrometric by increasing the proportion of meal ; in other words, making the poultice thicker. This is true, but at the same time it would be heavier, and it would be both cruel and useless to try to persuade a person suffering from phlegmon or peritonitis to keep a heavy weight on the affected part. The second condition, therefore, of a poultice is to be as light as possible, so that the place which is inflamed and in pain should easily endure this therapeutic means of cure.

The "vegetable powder" presents this double advantage, being very hydrometric and absorbing much water it can be used in small quantities, forming a soft and very damp paste, and further, by reason of its slight bulk, very light. But besides this, the specific gravity of the powder is less than the linseed meal, so that lightness is added to persistent humidity to make of a poultice prepared from this substance a typical production.

Let us add, that linseed meal contains acrid matter which excites the skin, and a fatty oil, which, in contact with the air, absorbs oxygen, developes fatty acids, and, so to speak, produces rust, another cause of cutaneous irritation. The "vegetable powder" is less exposed to produce this last phenomenon. We do not say that the inconvenience is entirely obviated, but we believe that it is less than when linseed meal is employed.

The first impression which the patient experiences to whom a poultice made of this powder is applied, is a sensation of freshness ; in a few moments a slight reaction supervenes, heat arrives, but this is not great, and is merely temporary, freshness soon returns, and remains as long as the application lasts : this may be prolonged for a considerable time on account of the light weight of the poultice.

Poultices of this description have recently been applied to a case of an infant affected with peritonitis, in a case of phlegmonous erysipelas, of two persons with abscess of the armpit, of several females affected with metritis or metro-peritonitis, and in one of phlegmon of the breast ; also of a patient who had suffered upwards of a year with scrofulous ulcer of the arm,—in each instance with complete success.

Samuel on Inflammation.

In *Virchow's Arch.*, Oct., 1870, Dr. Samuel speaks of the results of inflammation artificially excited by means of caustics, burning, or rubefacients. He affirms that he has observed how that the first phenomenon of the inflammatory process is the coagulation of blood in the veins ; to which there may succeed a secondary congestion in the arteries, by the impediment caused in the circulation From this he concludes that in the veins we must look for the principal factor of inflammation.

The Medical Council is to meet on the 29th. Dr. Burrows will bring before it the Scheme of the English Colleges, on behalf of the Royal College of Physicians.

The Queen has appointed Sir W. Gull to be one of her Physicians Extraordinary.

Amongst the curious publications called forth by the Prince's illness we have received a tabular statement entitled "The Nation's Wave of Suspense in 1871," and which is described as a loyal record of the critical illness of H.R.H. Albert Edward, Prince of Wales, with a conspectus of the bulletins issued by the Physicians in attendance, and notices of contemporary and connected events, exhibiting in a novel and striking form, and at one view the rising hopes and anxious fears of the British people during this period of national trial. For those who desire to thus commemorate the period there is an edition on plate paper for framing. It is a curiosity in its way, and we suppose will sell.

St. Mary's Dispensary, founded five years ago by Mrs. Garrett-Anderson, M.D., has been transformed into an hospital of which two wards are already opened. The Earl Shaftesbury presided last Thursday at the opening ceremony, and it appears that Dr. Elizabeth Blackwell, who has returned from America, and Miss Morgan, M.D.

Zurich, have joined Mrs. Anderson as physicians to the Hospital. We are not informed how these ladies are to obtain a British diploma, or how their names can be inserted in the *Register*, the only legal authority to practise.

◆

FINANCIAL POSITION OF GOVERNMENT IN RELATION TO ARMY MEDICAL DEPARTMENT.

Number of Medical Officers in each rank, with pay thereof, on May 1st, 1871.

No.	Rank.	Pay per Annum. £	s.	d.
101	Surgeon Majors	43,329	0	0
235	Surgeons	85,775	0	0
1	Assistant-Surgeons over 15 years	319	7	6
231	Assistant-Surgeons ,, 10 ,,	63,236	5	0
241	Assistant-Surgeons ,, 6 ,,	54,978	2	6
137	Assistant-Surgeons under 6 ,,	25,002	10	0
946		£272,640	5	0

Number of Medical Officers in each rank with pay thereof *as will be* on May 1st, 1876.

No.	Rank.	Pay per Annum. £	s.	d.
212	Surgeons Majors	92,856	0	0
124	Surgeons	44,895	0	0
117	Assistant-Surgeons over 15 years	37,366	17	6
229	Assistant-Surgeons ,, 10 ,,	62,688	15	0
137	Assistant-Surgeons ,, 6 ,,	31,253	2	6
127	Assistant-Surgeons under 6 ,,	23,177	10	0
946		£292,237	5	0
	Excess, £	19,597	0	0

The foregoing figures distinctly prove that at the present rate of promotion, the *position* of the component members of the Department must, at the expiration of five years, be so altered by length of service as to cause the gradually increasing outlay to have then reached an additional cost of nearly £20,000 per annum.

In this calculation no count has been taken of the number of surgeon-majors over twenty-five years' service, whose pay is consequently augmented by 3s. a day (viz., 27s.), as this sum is allowed to be a set-off against the probability of any deaths amongst the senior Assistant-Surgeons, whose places would then be supplied by those on a lower rate of income.

The calculation is thus rendered perfectly incontestable, and a continuance of the investigation will also show that each succeeding year must, by a process of reduplication, add immensely to the increasing price of the Medical Service.

It is therefore evident that on this day five years (May 1, 1876), the country will possess an Army Medical Staff of the exact numerical strength of to-day, but costing £20,000 more; and that for this augmented outlay nothing but discontent and dissatisfaction amongst those who are growing old in the subordinate grades will be purchased, without even adding a single man to a projected Medical reserve.

The solution of the difficulty is not only feasible, but possesses the rare qualification of being benefical alike to the State and to the Service.

Viz.:—Optional retirement at twenty years' service, instead of twenty-five, on £1 a day, *conditional* on enrolment, up to the age of 55 years, in the Medical Reserve, from which the Militia could be provided with experienced military surgeons, on additional allowance to each officer, when so employed, of quarters, fuel, servants, and forage.

Paradoxical as the statement may seem, it is nevertheless a fact that the retirement of a Surgeon-Major on £1 a day costs the State *only* 8s. 6d.; since, by his removal, 24s. being saved, while the promotion of an assistant-surgeon over fifteen years' service to the rank of surgeon, costs only 2s. 6d., and the appointment of an assistant-surgeon to fill the place of the latter 10s. a day, this sum, 12s. 6d., with the 20s. given as *pension* to the Surgeon-Major, represents a total loss of 32s. 6d. against a gain of 24s., leaving a balance loss of 8s. 6d., at which rate, for the increased outlay of £20,000, 129 Surgeon-Majors might be *pensioned* yearly.

It is therefore incredible that the excess of expenditure should still continue to be dispensed to the hardship of the recipients, when a proper utilisation of a far less amount would reproduce a normal rate of promotion, establish a Medical reserve, supply Medical officers for the Militia, and give rise to contentment in a Department where despair and stagnation now reign.

Foreign Medical Literature.

A REMEDY FOR CORYZA.

By Dr. C. Barbier.

(Translated expressly for the Medical Press and Circular from the *Lyon Médicale.*)

"Il ne faut pas négliger les petits profits."

I know a man who had one evening the foolishness to go to bed in a room where there was a large open fire of anthracite under a chimney half-closed by a slide. This imprudence almost cost him his life, but he only lost by it—immortality in the little journal of his arrondissement—a fine occasion lost. Hardly was he in bed, and not yet asleep, when he felt himself seized with pain, dizziness, shooting pains in the temples, &c., aiding thus with clear conscience the approach of a commencing nightmare. It is the effect of the charcoal, he thought, I must flee. But already he had no longer the power.

Soon overcome by a heavy sleep, he saw himself pursued, then martyrised by savages, he felt in the skin of his head the knife which scalped him . . . . until at last, rolling down a precipice, he awoke . . . . on his falling out of bed.

At this moment I awoke (I was the man) uttering an energetic Thank God! I heard eleven o'clock strike; I had gone to bed at nine.

It is impossible to tell what I suffered during those two hours; it is unspeakable. I appeal to all those who have entered the antechamber of the house of death, at the invitation of *carbonic acid*, of *carbonic oxide*, or of a simple *vase of flowers.* Ah! truly, can't please the lovers of romance who have made suffocation "the easiest death." I do not congratulate the ladies "deceived and abandoned" for their good taste and their monopoly for this kind of suicide.

Immediately upon my feet, I hastened to open the window and the door, to extinguish the fire, &c. But, alas! during the few minutes this manœuvre lasted, my room was filled with night fog, whilst my *inexpressible*, (free translation, my night-shirt) floated at will of the wind.

The following day I breathed needles in my parchment nostrils; I had a complete *rhinitis*, and expected bronchitis and the rest. Total, a six weeks' cold . . . . if I do not anticipate.

Immediately I rung for my groom.

"Understand," I said, "I shall not go out to-day, I shall strike work."

"Whether any one asks for me or not, I am at home to no one. Everyone is comprehended in the order I give."

A violent ring at the bell answered my last words; a pressing case in an urgent patient admitted neither reasons, nor excuses, nor replies; I must set out at once, in abominable weather . . . the consequences may be imagined.

The pocket handkerchiefs with which I had provided myself were soon useless . . . I was reduced to sponge the end of my nose, which was at first a relief to me, then a subject of study.

The more one blows one's nose, the more one wants to blow one's nose. The depletion of the nasal fossæ constitutes at first a subtraction of pressure which should facilitate a new exudation; besides, the *pituitary* membrane being exposed, the air inspired by the nostrils excites it grievously, which augments still more its hypersecretion, fresh need to blow one's nose, fresh vicious returns of the causes, reproducing the same effects, and this abundant serous secretion quickly constitutes a general enfeeblement, a veritable *autophagy*.

Let a pretty just comparison be allowed me, although a little *pulled in by the hair:* the more one has one's hair cut, the more it becomes long, thick, and strong; it is for the razor and the scissors that the impatient young man and the intelligent mother ask: he, moustaches; she, hair for her daughter.

The sensation of fulness of the nasal fosses is very unpleasant; it makes the voice snuffling or nasal; it changes voluntarily, by the fact of an error of pronunciation, a compliment into an absurdity, or even into an insult. . . . But that is a detail.

The accumulation of the nasal mucus concurs in fulfilling the conditions of the treatment of coryza extolled by M. Ivonneau, of Blois, the occlusion of the nostrils during forty-eight hours; besides, there seems to me to be, in rhinitis, the happy influence of the shedding of tears in acute ophthalmia; and it is known that M. Brachet preferred tears to all the *collyria*, and that he was not afraid, in the complication of xerosis, to provoke them by tickling the conjunctivæ with the head of a pin or the feather of a quill pen.

I see in it, besides, a plastic and warm layer preserving the membrane of Schneider from the contact of the air, smoke, irritating dust, &c., whilst maintaining the uniform conditions of heat and hygrometry, and, in fine, all the advantages of the method of dressing wounds by occlusion of M. Chassaignac, and of dressings more and more seldom in the order of the day in the course of the great operations of surgery (*a*).

To return from my digression, it was wearisome to me to enter my house to try the abortive method recommended in 1845 by the English Pretty (*b*).

Dr. Teissier has found it useful. He wrote it to a young lady the evening before her marriage, and she was thereby enabled to go through the next day's ceremonies without sneezing.

Instead of employing nitrate of silver in solution, I have reduced it to an impalpable powder, and mixed it with ten times its weight of sugar. Five or six inspirations of the size of about half a pinch of snuff of this powder have sufficed to avert in two days my cold in the head and its consequences. The first inspiration was very painful, and seemed to me to augment the illness, but the following were less and less so.

In the presence of this marvellous cure, I had one day the bad thought of inserting daily in all the journals of France the following advertisement:—

"A priest has found the means of curing colds in the head in twenty-four hours. The treatment exacts neither repose nor diet; it is easy to pursue in secret or on a journey. By sending (*sic*) 3 francs in postage stamps, &c. . . ." There is no doubt that this dodge would bring me a hundred francs a day. But . . . suffering humanity before all. . . . Wherefore I publish here *gratuitously* my method, which I summarise as follows:—

1st. Recommendation: During all the course of the malady *the patient must not sneeze* (*a*); if it is not possible, he must open his mouth wide, in order to expel by this cavity the column of air which would shake the partitions of the nasal fossæ too strongly.

2nd. Invitation: One must blow one's nose as little as possible, and in an incomplete manner, for the numerous reasons indicated above.

3rd. Prescription: Three or four times a day, until an effect, draw in strongly by the nostrils, a very small pinch of the following powder:—

Nitrate of silver dissolved . .	1 part
Sugar	9 parts.

Reduce to an impalpable powder.

I finish, Mr. Editor, with asking you to be so good as to insert this little article in a corner of your charming journal. It is not very well written (not the journal, the article), I know, but I also know that

One must not neglect little benefits.

◆

Literature.

SYPHILIS: ITS NATURE AND TREATMENT, WITH A CHAPTER ON GONORRHŒA (*b*).

We bespeak a cordial welcome for this new work, which contains in a moderate compass the conclusions of an industrious, pains-taking syphilographer, with an unbounded courage of convictions, and a great familiarity with the whole literature of the great subject to which he has devoted so much labour.

In the preface the author explains his motives for writing another work on a subject already so much dilated upon. It seems that, in 1863, he published a pamphlet which soon went out of print, but which was referred to in various debates on the treatment of syphilis in London, Paris, and Christiania. It was also translated into German by Dr. Hermann, of the Wieden Hospital, Vienna. He seems to think that the evidence contained in the pages of this work may tend to convince all who read it, that mercury has been credited with far too much remedial power over syphilis, by the past generation of medical men; and that iodine and iodide of potassium are so much more safe and useful, if used in right doses, that it is likely that mercury may be ere long almost entirely discarded from the treatment of all forms of the disease. Open discussion of such obscure points is, he adds, not only a right, but the duty of all who desire to come to any clear conclusion.

The first two chapters, as far as page 33, are devoted to the doctrines and treatment of gonorrhœa; firstly, in the male, and secondly, in the female. Chapter III. is "On Syphilis," and thirty-five pages are given to the general consideration of the whole doctrines of syphilis and its phenomena. Chapter IV. is "On Syphilis in Women." Chapter V. is "On the Diagnosis and Causation of the Disease." In Chapter VI. the author treats of the treatment of syphilis. Chapter VII. continues the same subject. In Chapter VIII. there is, in the form of an Appendix, a disquisition on the "Origin of Syphilis, and Nature of the Chancre."

With regard to gonorrhœa, the author calls it a *special* inflammation of the urethra, of which by far the most

---

(*a*) How many amputated on the field of battle have owed their most prompt cure to the want of care—that is to say, to the material impossibility of making methodic dressings?

It is not the more or less prolonged remaining of pus on a wound which favours purulent resorption; it is autophagy. Let us make our patients eat as the English do, and count a little more on *natura medicatrix*.

(*b*) Cauterisation of the nasal fossa with—

Distilled water, 30 grammes,
Nitrate of silver, 40 centigrammes.
Mix.

(*a*) There is a means of avoiding the disagreeableness of sneezing, that is by rubbing briskly the sides of the nose with the fingers (T. and D.); but in sharp rhinitis this means is painful, and produces a contrary effect.

(*b*) "Syphilis: Its Nature and Treatment, with a Chapter on Gonorrhœa." By Charles R. Drysdale, M.D., M.R.C.P.Lond., F.R.C.S.Eng. Physician to the Metropolitan Free Hospital, London, &c. Late Hon. Sec. to the Harveian Society's Commission for Prevention of Venereal Diseases. London: Baillière, Tindall, and Cox. 8vo. Pp. 165.

ordinary antecedent is contagion. Perhaps ninety per cent. of all cases come from contagion. However, he admits that it is true enough what M. Ricord says, that there is nothing more common than to find women who have communicated the most acute attacks of gonorrhœa to the male, and who are only affected with a scarcely purulent catarrh. Excesses in venery and alcoholic fluids will, however, sometimes cause gonorrhœa. Mr. H. Lee's opinion that gonorrhœa in the male may arise from intercourse with a woman in whom no change in the genital organs can be detected on minute examination, is adopted by the author.

Gonorrhœa has a short incubative period, may continue for years, and is the main cause of stricture of the male urethra. It tends eventually to become chronic in the form of gleet, and at any moment to relapse again when alcoholic fluids are indulged in. The phenomena observed by the endoscope are redness in the fossa navicularis, or in the membranous or prostatic portions of the urethra, &c. In chronic cases, the colour of the mucous membrane is dusky, less elastic, firm, and even leathery, and twice or thrice as thick as in health. With regard to treatment, the sole treatment which the author evidently much approves of is, that of injections. At the outset, strong injections of nitrate of silver sometimes do cut short the disease (ten grains to the ounce); but these are rather dangerous. Chloride and sulphate of zinc make the best of all injections (two grains to the ounce, or thereabouts). They may be used at all stages of gonorrhœa, if care be taken. Our author seems to have a complete distaste for copaiba and cubebs in all but the most exceptional cases. The use of hot fomentations of the organ is very useful in the acute stages. For chordee, one third of a grain of morphia is useful at bedtime. Injections to be used thrice a day at least, the fluid retained three minutes, and continued for a week after the discharge has ceased. In chronic obstinate cases, passage of a bougie daily is good practice. The endoscope is too cumbersome for practice. Balanitis may be treated by a lotion of liquor calcis. Prostatitis requires warm baths, rest, and warm water enemata. In cystitis, infusion of buchu is useful. In orchitis, rest in bed, the testes being well raised, a brisk purge, and hot fomentations are recommended. Gonorrhœal rheumatism is not very uncommonly met with. No internal treatment is useful. Blistering of the painful joints should be tried. Gonorrhœal conjunctivitis is a most dangerous prognosis. Incisions of the conjunctiva are required with cautery, with nitrate of silver. Gonorrhœa has scarcely ever anything to do with syphilis, except when a chancre is in the urethra.

As to stricture of the urethra, it is very rare indeed in the prostatic portion, and may be single, multiple, cartilaginous, or undilatable. Stricture may involve the canal to the extent of half an inch, or for several inches. The chief cause of stricture is gonorrhœa, but cautery, with strong solutions of nitrate of silver for spermatorrhœa, may produce it. The French scale of bougies is more gradual and better than the English, and should be used in treating stricture. Two to four days should elapse before the next size is passed, and No. 26 or 28 of the French scale should be passed before concluding. Holt's dilator has much to be said in its favour, especially in the treatment of the poorer classes; who, if not cured at once, often die of retention of urine from carelessness. In suitable cases there is very little danger, indeed, from forcible dilatation. The rigors of stricture patients should be treated by large doses of quinine. In Chapter II., the author says that much obscurity exists with regard to the diagnosis and cure of gonorrhœa in the female. So much is this the case that he evidently would not like to assert categorically that any given female patient was suffering from gonorrhœa, unless there were vulvitis accompanied by vaginitis and urethritis. The last symptom is, doubtless, a useful one to aid the practitioner in coming to a conclusion. The chief treatment for gonorrhœa in the female consists in warm fomentations, when the attack is acute, followed by strong injections of sulphate of zinc, alum, and tannin. In urethritis, a thin pencil of nitrate of silver may be passed up the urethra. In gonorrhœa of the uterus, a sponge-tent, or a tent of laminaria, should be passed, and then the interior of the uterus touched with tincture of iodine. Gonorrhœa is the main cause, probably, of the infertility of prostitutes. Gonorrhœa in the female is not easily differentiated from syphilitic discharges proceeding from mucous tubercles, &c.

In Chapter III., the author remarks that in Paris, physicians now are the chief persons who attend at the Venereal Hospitals, since syphilis requires but few operative procedures. It is evident that he casts in his lot with the school of dualists; although, both in this chapter and in the appendix, our author certainly gives both sides of the question fairly. Notwithstanding all that has been written, there can be little doubt that cases do often occur, even in the male, in which it is very difficult to give a certain prognosis as to whether syphilis will follow after a given ulcer or not. The author does not believe that slightly indurated sores are specially likely to be followed by benignant syphilis. Women suffer far more severely from chlorosis, loss of hair, and, indeed, from many others of the horrors of the disease, than men do. The alopecia of syphilis is caused by the *fever*, or want of nutrition of the body. Phagedænic sores are often the preludes to rupia. Roseola is almost always seen among the early rashes of syphilis. The papular form of syphilitic eruption is very common. The pustular is common on the scalp. Squamous syphilitic eruptions are not uncommonly mistaken for psoriasis, but are rarely itchy. There is a pigmentary skin disease seen in some cases. Mucous tubercles are pathognomonic of the disease. They are common on the throat and in the nostrils; but rare in the larynx. Elevated patches on the tongue are common in early syphilis. Vegetations or warts have no necessary connexion with syphilis. The glands affected in syphilis are chiefly the inguinal, cervical, occipital, axillary, and popliteal. Jaundice sometimes occurs in early syphilis, and hemiplegic seizures have been noticed by the author. Syphilitic iritis is a most important disease. It lasts a long time, and requires careful local treatment above all. In young adults the prognosis is not unfavourable; but in elderly persons it not unfrequently destroys vision from adhesions of the iris to the lens, &c. Syphilitic iritis is very liable to relapse. It is not uncommon in infants, and often causes blindness in infancy, when untreated. Choroiditis and retinitis are seen in early syphilis, and occasionally cases of mydriasis are met with.

Acute rupia may cause death from cachexia; but, fortunately, *malignant syphilis* is comparatively rare now-a-days. Diseases of the liver and kidneys sometimes follow rupia. Small tumours of a dusky red colour form in the secondary period, perforate the skin, and cause phagedæna. Gummy tumours are very common in the tertiary period in all parts of the body, but the throat is their seat of predilection. Iodide of potassium is, the author thinks, all but infallible in such cases. Dry caries of the skull is sometimes, though rarely met with in syphilis; but since iodine has taken the place of mercury, such cases are not so dangerous. Persistent headache, conjoined with prominences and depressions of the skull, may make us diagnose such cases. The cartilages of the larynx are occasionally involved by syphilis, and in hereditary syphilis. The joints are very rarely attacked in syphilis of adults. As to gummy tumours of the testes they are not very rare, and fortunately yield rapidly to large doses of iodide of potassium. The ovary is occasionally attacked by gummy tumour, but not often. As to syphilitic Bright's disease, this is occasionally met with, and the author relates a fatal case under his care at the Metropolitan Free Hospital.

Thickening of the pylorus has been referred to syphilis; and ulceration of the rectum is occasionally caused by syphilis, with stricture of a fatal character. The liver is not unfrequently attacked by the disease; and the author relates one or two cases in which he made the diagnosis of syphilitic liver. Iodide of potassium is very useful, he thinks, in such cases. The heart and great vessels are *doubtless sometimes* affected with gummy products, and aneurism of the aorta is due to syphilis in some cases. Dr. Drysdale mentions that he has had some cases of syphilitic lung disease at the North London Consumption Hospital, which were accompanied with cavities, and one of which did well with iodide of potassium. Diseases of the nerves are now recognised very frequently to be due to syphilis. Epilepsy in adults, especially in males over thirty, is not unfrequently syphilitic in its origin. Such epilepsy is usually accompanied by unilateral convulsions. Iodide of potassium cures those cases sometimes very rapidly. Paraplegia and locomotor ataxia also are not unfrequently of syphilitic origin, and the iodide is useful in suspected cases. Hemiplegia syphilitica is not uncommon. Ptosis is very commonly caused by syphilis. The optic nerve, the third and fifth nerves, are all commonly attacked by this terrible malady; the facial nerve, too, is sometimes attacked late on in the disease. Tic doloureux, when very persistent, should be treated by iodide of potassium, as it is sometimes syphilitic. Ozæna is one of the most difficult of all the affections caused by this disease to treat successfully. Large, very large doses of iodide of potassium, however, almost always succeed. The epiphora caused by inflammation of the lachrymal canals, is best treated by the iodide, as is also the interstitial corneitis seen so commonly in young persons who have inherited this disease, and show it near the time of birth. Cataract is not rare in inherited syphilis. Atrophy of the vessels within the eyeball and in the papillæ may cause blindness in tertiary syphilis. Deafness is caused chiefly in cases of hereditary syphilis.

(*To be continued*).

Correspondence.

THE SMALL-POX IN DUBLIN.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Dear Sir,—Judging from the number of admissions during last week, I consider the epidemic continues, though slowly, to decrease. I have had since Saturday last but nineteen fresh cases. No doubt the cause I pointed out in my last letter, viz., the opening of the Mater Hospital for small-pox cases, contributes in a great degree to produce the result of diminishing, very considerably, the admissions into the sheds; still, even taking this into account, the average weekly number of fresh cases is, I think, decreasing. I am more disposed, however, to regard the gradual, and, as far as I can judge, permanent decrease, in the number of purpuric cases, as a more certain sign of the fading away of the epidemic than the mere diminution in numbers might lead one to conclude. Of the nineteen admitted during the past week there was only one well-marked purpuric case. The proportion of confluent cases continues about the usual average. Another circumstance, to which I think considerable importance must be attached, is the fact that the disease now appears to show a tendency to attack, in a greater ratio than previously, those who have *never* been vaccinated. Five out of the nineteen cases admitted last week were never vaccinated. Taking twenty cases, at random, of those admitted at the commencement of the epidemic, I find that only one out of that number was so unfortunate as never to have been vaccinated. It is true that the large proportion of unvaccinated cases, last week, may be merely an accident, and before drawing any definite or safe conclusion from the fact, it would be necessary to ascertain if a similar condition of things prevailed in the other hospitals of the city. As far as the fact may be taken as evidence, the conclusion it seems to warrant is, that the epidemic, having expended much of its force, now finds its victims to a greater extent than formerly amongst those who have never had the protection of even primary vaccination; that in fact, vaccination, even when performed long since, becomes a more powerful protecting influence as the epidemic decreases, and that hence a falling off in the proportion of vaccinated to unvaccinated persons attacked is evidence, so far, of a general decrease of the epidemic. I believe it is true that in an invasion of cholera one of the first signs of its subsidence is a lessening in severity of the individual cases, and the same appears probably to be true of small-pox.

Yours truly,
Jos. E. Kenny,
Union Physician, North Sheds.

Saturday evening, Feb. 24th.

POISONING BY CARBOLIC ACID.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—In the last issue of the Medical Press there is reported by Dr. Harley a case bearing the above heading, and in which he asks for some "information on the subject, especially as to the best antidote for it." Now if you would not deem it unworthy your journal, the following few words on a case somewhat analogous to Dr. Harley's may not be devoid of some notice. About a year hence a little boy, æt. eighteen months was brought to me suffering from a severe burn on the side of face and neck down to clavicle. I prescribed for it a liniment, consisting of one part carbolic acid to twelve of olive oil, and pledgets of lint steeped in this to be applied to the affected surfaces. Under this treatment for some days everything went on quite well, and considerable portion of surface had healed, when one morning the mother used the dressing so strong, that immediately the child was taken violently ill. In a few minutes afterwards I saw the child, and believed it had not many moments to live, it was collapsed and a profuse "milky froth" flowing from its mouth, no vomiting, I had it brought into the open air, and directed the mother to keep the froth carefully wiped from the mouth; while I administered myself a teaspoonful of spirits as a *dernier ressort*, for as I have said, I thought it had not many moments to survive. However, it rallied perfectly in the course of an hour, and made a complete recovery. The parts to which the dressings were applied were rendered "perfectly white," and the oozings from them, that came in contact with the sound skin of the neighbouring parts, caused excoriation of them.

I am &c.,
John McKeogh, L.R.C.P.,

Thurles, 16th Feb., 1872.

THE CONTAGIOUS DISEASES ACTS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—The Editor of the *British Medical Journal*, in a recent number of that periodical, animadverts, with the warmth and earnestness of a partisan, on Mr. Bruce's change of policy on the subject of the so-called "Contagious Diseases Act;" and characterises this change of policy, as a pusillanimous retreat from a position which had been previously maintained against a "senseless and indecent agitation."

How far it is prudent and discreet in the Editor of a public journal, to give an *ex parte* complexion to his official utterances, on a subject as to which there is anything but unanimity among the members of the Profession, it is not for me to determine, but I may be permitted to express my conviction, that, if a comparison were to be instituted as to the relative intelligence of the abettors of that measure, and its opponents—setting aside those members of the profession who would be in the division—the result would furnish a very fair average as to the latter class; whilst among them not a few would be found, in mental calibre, in force of intellect, and in sobriety of judgment, not inferior to any of its advocates. How this sweeping charge of "senselessness" could have been uttered and entertained in the face of such an opposition, can only be charitably explained on the supposition, that the intellect of the parties concerned had suffered a temporary disturbance.

The latter taunt of the two reverts, by its inherent resilience, upon the persons who have given expression to it. A bill introduced for a partial and inequitable application, and surreptitiously placed upon the statute book under a vague and fictitious designation, must have had in the minds of its framers and supporters certain phases of indelicacy unsuited for the visual faculty in the broad light of open day. Besides, assuming that a nation, professedly Christian, recognises the injunctions of the Decalogue as the basis of its code of morals, to indorse, by parliamentary enactment, a course of licentiousness, as it directly contravenes the supreme authority of the Great Lawgiver on the subject in question, so it can never promote the interests of the community, social and physical, untimely associated as they are with its moral interests.

In submitting the above for insertion in the MEDICAL PRESS AND CIRCULAR, I am echoing, as I believe, the sentiments of many members of the association to which I belong, who are equally alive to the physical evils which are being entailed by syphilitic taints in the constitution, but who have a profound conviction, that that which in principle is morally wrong, can never be made a remedial agency for the consequences of a course of vicious indulgence.

I am &c.,
J. BIRCHENALL, M.R.C.S.,
Macclesfield, Feb. 19th, 1872.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I have heard it stated as the opinion of a late Medical professor of Queen's College, "that black clothes received and retained the infection of diseases, more than any other colour," thus resembling the rays of heat, and light, which we know are absorbed by black. Can you or any of your correspondents throw light on this interesting question?

Armagh, 15th Feb., 1872. M.D.

Medical News.

Royal College of Physicians of London.—At an extraordinary meeting of the College on Monday, the 19th ult., the following gentlemen having conformed to the by-laws and regulations, and passed the required examinations, were granted licences to practise physic, including therein, the practice of medicine, surgery, and midwifery:—Edward Cresswell Baber, M.R.C.S., 34 Thurloe square, S.W.; Robert Edward Hammond, M.R.C.S., 17 Booth street, E., Chorlton-on-Medlock; John Nelson Kiddle, M.R.C.S., Guy's Hospital; Charles Sage Ticehurst, 11 Carlisle parade, Hastings; John Tweedy, University College Hospital; George Bland, who passed his examination in medicine, October, 1871, and has obtained a recognised qualification in surgery.

Mr. Norman Lockyer on the Sun.—On Wednesday evening, Feb. 14th, the president, vice-president, and managers of the London Institution, Finsbury circus, gave a conversazione, which was attended by several hundred persons, including a large proportion of ladies. Among the contributions for the occasion on view in the spacious Library were a series of water-colour sketches of Mexican scenery and vegetation lent by Mr. G. H. White; photographic views of the Nile, belonging to Mr. F. M. Good; spectroscopes, rare chemicals, new voltaic batteries, &c., the special feature, however, of the evening was a lecture by Mr. J. Norman Lockyer, F.R.S., on the Sun, illustrated by interesting drawings and photographs of the exterior of that luminary, as seen under various aspects, including prominences, lines, and other phenomena. The lecturer's remarks naturally had special reference to various points connected with the atmosphere and vapours around the Sun and the enormous forces which have recently been discovered to be constantly operating. Having alluded to and illustrated the discovery by chemical means of hydrogen, magnesium, and other substances outside the Sun, Mr. Lockyer said that in future the study of the heavens must be the combined work of the astronomer, the physicist, and the chemist; and pointed out the necessity of closely studying, not merely the visible part of the spectrum, forming but a small part of the whole, but also what is beyond. In conclusion, he contended that if a case had been made out in favour of the Sun's atmosphere, some steps should be taken in order that the question might be more closely investigated and more rapidly worked out than it is now.

The last report of the Sanitary Commissioner for Madras gives the following table of mortality in that presidency:—

In the European Army - - - -	19·2	per thousand.
In the Native Army - - - - -	13·8	do.
Civil population- - - - -	18·5	do.
Police - - - - - - -	13·5	do.
Prisoners - - - - - - -	26·5	do.

There has been a remarkable decrease in the death-rate, since the prisoners have been provided with better food and more room. In 1865, the death-rate, sad to say, was 126·3 per thousand; but in 1870, after the introduction of improvements by which the prisoners were provided with less impure air, with better food, and pure water, it fell to only 26 per thousand. The *Madras Medical Journal* says that these figures are a full and sufficient answer to those who, from time to time, have raised an outcry against pampering our prisoners, and they must satisfy all right-minded and impartial minds that the recently effected improvements were absolutely necessary to wipe out a very black blot from our prison administration, seeing that, under former insanitary conditions and surroundings, our prisoners were literally decimated with scurvy and its allies, and that, in the majority of cases, a prolonged term of imprisonment was tantamount to a sentence of death.

Preservation of Meat.—The Food Committee of the Society of Arts have had before them some further specimens of Bancroft's desiccated meats, from Queensland. It consists of meat deprived of a certain amount of water, by five pounds of fresh meat being reduced, by a simple drying process, to one pound. It is ground to a powder, and, with no mixture of any other ingredient, is put into tins, not air-tight, but simply covered with an ordinary lid. The Committee can speak confidently of its keeping qualities, the specimens which they have had before them being part of the original consignment sent to this country in 1867. It is in excellent condition, just as good as when originally sent over. It contains all the constituents of the meat, and is well adapted for the making of soups, beef-tea, potted meats, hashes, curries, &c., &c. In flavour it is agreeable, and its nutritious qualities have been favourably certified to the Committee by Dr. A. S. Taylor, to whom it was sent for examination. The Committee would gladly see it introduced into the trade as a general article of food, believing it a valuable addition to the food resources of the kingdom.

Army Medical Department.—Inspector-General Beatson embarks for Bombay about the 6th inst. Staff Surgeon-Major Bawtree has been granted leave of absence pending his retirement upon half-pay. Staff Surgeon Titterton, having been placed under orders for the West Indies, has been pronounced by a medical board unfit for tropical service for the present, and has proceeded on six months' leave. Staff Assistant-Surgeon T. W. Wright has been granted one year's leave, after a tour of service on the African Coast. Staff Assistant-Surgeon S. Robertson proceeded on leave on the 1st inst. until March 31st on private affairs. We understand that the strength of the department at Malta and Gibraltar is to be at once reduced. Surgeon-Major James E. Scott, M.D., 4th Battalion, Rifle Brigade, is acting as principal medical officer at Chatham, in addition to his other duties. Assistant-Surgeon Isaac Hoysted, 2nd Battalion, 9th Regiment, and Assistant-Surgeon J. C. Murphy, R.E., have rejoined at Chatham from leave. Staff Assistant-Surgeon Beattie has been ordered to the Isle of Grain, to take medical charge of troops at that station. Assistant-Surgon A. Minty, M.B., being supernumerary in his regiment the 4th Battalion, Rifle Brigade, is about to be transferred to the staff.

Science at Cambridge in 1872.—The following is a list of the scholarships and exhibitions for proficiency in Natural Science to be offered in Cambridge during the present year:—*Trinity College.*—One or two of the value of about £80 per annum. The examination will be on April 5, and will be open to all undergraduates of Cambridge and Oxford, and to persons under twenty who are not members of the Universities. Further information may be obtained from the Rev. E. Blore, Tutor of Trinity College. *St. John's College.*—One of the value of £50 per annum. The examination (in Chemistry, Physics, and Physiology, with Geology, Anatomy, and Botany), will be on the 12th of April, and will be open to all persons who have not entered at the University, as well to all who have entered and have not completed one term of residence. Natural Science is made one of the subjects of the annual College examination of its students at the end of the academical year, in May; and Exhibitions and Foundation Scholarships will be awarded to students who show an amount of knowledge equivalent to that which in Classics or Mathematics usually gains an Exhibition or Scholarship in the College. In short, Natural Science is on the same footing with Classics and Mathematics, both as regards teaching and rewards. *Christ's College.*—One or more, in value from £30 to £70, according to the number and merits of the candidates, tenable for three-and-a-half years, and for three years longer by those who reside during that period at the College. The examination will be on March 19th, and will be open to the Undergraduates of the College; to non-Collegiate Undergraduates of Cambridge; to all Undergraduates of Oxford; and to any students who are not members of either University. The candidates may select their own subjects for examination. There are other Exhibitions which are distributed annually among the most deserving students of the College. *Caius College.*—One of the value of £60 per annum. The examination will be on March 19th, in Chemistry and Experimental Physics, Zoology, with Comparative Anatomy and Physiology, and Botany, with Vegetable Anatomy and Physiology; it will be open to students who have not commenced residence in the University. There is no limitation as to age.—Scholarships of the value of £20 each, or more if the candidates are unusually good, are offered, for Anatomy and Physiology, to members of the College.—Gentlemen elected to the Tancred Medical Studentships are required to enter at this College; these Studentships are four in number, and the annual value of each is £113. Information respecting these may be obtained from B. J. L. Frere, Esq., 28 Lincoln's Inn Fields, London. *Clare College.*—One or more of the value of £50 per annum. The examination (in Chemistry, Chemical Physics, Comparative Anatomy, and Physiology, and Geology) will be on March 19th, and will be open to students intending to begin residence in October. *Downing College.*—One or more of the value of £40 per annum. The examination (in Chemistry, Comparative Anatomy, and Physiology) will be early in April, and will be open to all students not members of the University, as well as to all undergraduates in their first term. *Sidney College.*—Two of the value of £40 per annum. The examination (in Heat, Electricity, Chemistry, Geology,'Physiology, Botany) will be in October, and will be open to all students who may enter on the College boards before October 1st. *Emanuel College.*—One or more of the value of £40 to £60 per annum. The examination on March 19th, will be open to students who have not commenced residence. *Pembroke College.*—One or more of the value of £20 to £60, according to merit. The examination in June, in Chemistry, Physics, and other subjects, will be open to students under twenty years of age. *St. Peter's College.*—One from £50 to £80 per annum, according to merit. The examination, on April 4th, in Chemistry, Comparative Anatomy, and Physiology and Botany, will be open to students who will be under twenty-one years of age on Oct. 1st, 1872, and who have not commenced residence. *King's College.*—One of the value of about £80 per annum. The examination, on April 9th, will be open to all candidates under twenty, and to undergraduates of the College in their first and second year. There will be one classical and one mathematical paper, in addition to three or more papers in Natural Science, including Physics, Chemistry, and Physiology. Although several subjects for examination are in each instance given, this is rather to afford the option of one or more to the candidates than to induce them to present a superficial knowledge of several. Indeed, it is expressly stated by some of the Colleges that good clear knowledge of one or two subjects will be more esteemed than a general knowledge of several. Candidates, especially those who are not members of the University, will, in most instances, be required to show a fair knowledge of Classics and Mathematics, such, for example, as would enable them to pass the Previous Examination. There is no restriction on the ground of religious denomination in the case of these or of any of the Scholarships or Exhibitions in the Colleges or in the University. Further information may be obtained from the Tutors of the respective Colleges. It may be added that Trinity College will give a Fellowship for Natural Science once, at least, in three years; and that most of the Colleges are understood to be willing to award Fellowships for merit in Natural Science equivalent to that for which they are in the habit of giving them for Classics and Mathematics.

Gleanings.

The Glue Bandage as a Primary Setting for Fractured Limbs.

Dr. George Ross, House Surgeon, Montreal General Hospital, says:—The use of the Glue Bandage as a primary setting for fractured limbs, has been introduced into this hospital by Dr. McCallum, within the past three months for the first time here, and as far as I am aware, for the first time also in this country. It may therefore be of interest to shortly record the following cases which were amongst the first so treated.

The method of applying the bandage being the same in all, one description of the general procedure will apply to all and avoid repetition. First then, it is necessary to procure some good suitable glue—the best for the purpose is Cooper's No. 1 white English glue, or else some of the finer sorts in thin sheets, which are manufactured in this country; it is prepared by first soaking in water for an hour or two, and then melting in a common carpenter's glue-pot; also some fine sheet wadding, and several rollers made of thin cambric or old worn cotton, (new cotton is objectionable for it will not soak up the glue so thoroughly, and will make a less firm bandage.) The limb is then entirely swathed in a thin layer of wadding made by splitting the ordinary sheets in the middle to avoid unnecessary bulk, and then whilst carefully held in position by an assistant, the first roller is applied in the ordinary way; this done, it is smeared all over by a brush, or better still by the hand, with a good layer of the melted glue to which one-fifth part of alcohol has been added to accelerate the evaporation. The second roller is then applied, and in like manner coated thickly with glue. Some strips of bandage ten or twelve inches in length, are then thoroughly soaked in the glue and placed over the seat of fracture, some vertically and others diagonally, so as to still further strengthen this part. The third roller is finally secured over the whole and covered with a thick coating of glue.

It is necessary now to sling the limb so that the air may have equal access on all sides to dry it. I have found that the outside coating will become quite dry in from three to five hours, when the sling may be removed, but the entire thickness of the bandage will not be found entirely consolidated for about forty-eight to sixty hours. After the lapse of this time, the leg is found to be encased in a perfectly-fitting boot, more solid than the thickest sole-leather, and can be moved in any direction without pain. In none of the cases has there been any complaint of pain from the swelling that we might expect to find occur shortly after a fracture had been sustained. On the contrary, the patients have all expressed themselves as feeling extremely comfortable. As soon then as the bandage has completely consolidated, it becomes necessary to split it down the front from one end to the other. Owing to the extreme hardness of the splint, this is a matter of some difficulty, except in the event of one's possessing a pair of powerful properly-constructed bandage-pliers: failing this however, the simplest plan is to slip a very thin piece of wood beneath it, and then cut on this with a sharp strong knife. Having thus split the bandage from end to end, a number of holes are bored on either side with a brad-awl, and a long tape being passed alternately through these, it is laced up like a lady's corset. The apparatus is then entirely complete, and may remain without being touched until union is perfect. The above description might lead some to suppose that the process was long and tedious, and in consequence objectionable, but our small experience with it in this hospital is such as to make us believe that by reason of its increased comfort to the patient, and of the facts that patients can sooner get up with safety with this than any other form of splint, and that it will never get out of order, and consequently never require re-adjustment, the advantages secured by its employment greatly counterbalance any slight trouble that it is necessary to take to ensure its proper application at first.

At this hospital, the above-described method has been put into practice in several cases of simple and compound fracture of the leg, and in all with most satisfactory results. In the majority of the cases, the patients were permitted to get up on crutches on the third day from the receipt of the accident. In two, it was thought advisable to make use of a box splint for a few days previous to the application of the bandage on account of considerable swelling and rapid vesication.—*Canada Medical Journal.*

The Alkaloids of Opium.

BY O. HESSE. (*a*)

In order to obtain the rarer alkaloids, the black mother liquors were taken (as obtained in the Robertson-Gregory process) from which the hydrochlorides of morphine, codeine and pseudomorphine had been separated. This liquor was first treated with an equal volume of water and precipitated with excess of ammonia; the clear liquor was exhausted with ether, and this again treated in the manner described in the *Ann. Chem. Pharm.* vol. cliii, p. 47. The alkaloids thus obtained can be now separated into two parts, the one insoluble, and the other soluble in excess of sodium hydrate. The alkaline solution, treated according to a former method, deposits first a small quantity of lanthopine, the filtrate from which contains neither codeine nor meconidine, for it is not coloured on warming with sulphuric acid; from it the author has obtained a small quantity of codamine. The solution is precipitated with ammonia, and the hard precipitate dissolved in a very small quantity of boiling dilute alcohol. White crystals are thereby obtained, from which the laudanine is separated by the action of hydriodic acid with which it forms a difficultly soluble compound. *Laudanine* has the composition $C_{20} H_{25} N O_4$, instead of the formula $C_{20} H_{25} N O_3$, as formerly given; its melting point is 166°. *Codamine* is found to melt at 126°, instead of 121°, and has probably the composition $C_{20} H_{23} N O_4$,

The portion insoluble in sodic hydrate, which must contain thebaine and papaverine, is dissolved in acetic acid, and the solution is neutralised in presence of alcohol, whereupon a crystalline precipitate is formed, consisting of papaverine and narcotine, which can be separated by oxalic acid. The melting point of *narcotine* is given by the author as 176°, instead of 170°.

Papaverine, $C_{21} H_{21} N O_4$, when absolutely pure, dissolves in small quantities of sulphuric acid without colouration; generally, however, on warming a crystal of papaverine with concentrated sulphuric acid, a dark blue colour is produced, but when other crystals are added the colour is not increased; on the addition of water, papaverine sulphate is precipitated, as a resinous mass, which after a short time solidifies. No other alkaloid of opium gives this reaction; pseudo-morphine, which is the only one that is precipitated from its sulphuric acid solution by water, is obtained as a crystalline powder, not a resinous precipitate. Dilute nitric acid converts papaverine readily into nitro-papaverine,

$$C_{21} H_{20} (N O^{2}) N O^{4} \div H^{2} O,$$

which occurs in colourless thin prisms, melting at 163°, and becoming yellow on exposure to light. When chloride of zinc and impure papaverine hydrochloride are allowed to act together for a short time, the impurities are decomposed, and a hydrochloride of an alkaloid is obtained, which agrees in properties with pure papaverine hydrochloride. The new alkaloid forms with acids very handsome crystalline salts, resembling the salts of cryptopine.

The neutralized acetic acid solution, from which the narcotine and papaverine have been separated, contains *thebaine*, which can be separated as the bitartrate by adding powdered tartaric acid. Instead, however, of tartaric acid, concentrated hydrochloric acid is added, which keeps the thebaine in solution, whereupon crystals of cryptopine hydrochloride are formed. From the dark coloured liquid still remaining, the author has been able to separate three other alkaloids, protopine, laudanosine and hydrocotarnine, by processes which will be described in another memoir.

Cryptopine, $C_{21} H_{23} N O_5$, melts at 217°, dissolves easily in chloroform, with difficulty in alcohol and is insoluble in ether. It is strongly basic, and forms salts which can be obtained in crystals; with hydrochloric acids it forms two salts $C_{21} H_{23} N O_5 . H Cl + 6 H_2 O$, and with $5 H_2 O$, but the author has not obtained the salt with $2 H Cl$, as found by T. and H. Smith. It is precipitated from cold neutral solution by hydrochloric acid as a gelatinous mass, but from hot solutions prisms are deposited.

Protopine, $C_{20} H_{19} N O_5$, may be separated easily from the former alkaloid; it forms solid prisms with hydrochloric acid. It melts at 202°, and is somewhat difficultly soluble in alcohol and insoluble in ether.

Laudanosine, $C_{21} H_{27} N O_4$, dissolves sparingly in cold, but easily in hot benzol; it forms colourless prisms which melt at 89°. It is easily soluble in alcohol and ether, and has a basic reaction; with hydriodic acid it forms a very difficultly soluble salt.

Hydrocotarnine, $C_{12} H_{15} N O_3$, crystallizes in large colourless prisms, with $\frac{1}{2} H_2 O$ as water of crystallization; they melt at 50°, and give up the half-atom of water. It volatilizes at 100° with partial decomposition, it dissolves easily in ether and alcohol; behaves like narcotine with concentrated sulphuric acid. Its reaction is basic, and it neutralizes dilute acids, forming salts which are easily soluble in water.

The author appends a valuable table, giving the colourations observed when the various alkaloids are dissolved in pure strong sulphuric acid, and in acid containing traces of iron.

	Dissolves in Pure Acid.		In Acids containing Oxide of Iron.	
	At 20°.	At 150°.	At 20°.	At 150°.
Codeine	Colourless	Dirty green ...	Blue	Dirty green
Codamine ...	Colourless	Dirty red-violet	Intense green-blue	Deep violet
Laudanine ...	Very faint rose-red...	Deep red-violet	Brown-red, similar to cobaltic nitrate solution	At first green, then deep violet
Laudanosine ...	Faint rose-red, somewhat stronger than laudanine	Ditto	Ditto...	Ditto
Cryptopine ...	At first yellow, then violet, and finally deep violet	Dirty green ..	Deep violet	Dirty green
Protopine ...	At first yellow, then red, and finally bluish-red	Dirty greenish-brown	Ditto...	Dirty-greenishbrown

---

MEETINGS OF THE LONDON SOCIETIES.

Wednesday, Feb. 28.—Royal College of Surgeons of England, 4 p.m. Prof. Flower, "On the Comparative Anatomy of the Organs of Digestion in the Vertebrata."

Royal College of Physicians of London, 5 p.m. Dr. Hensley, "On the Mechanism of Respiration, Circulation, and Digestion."

Thursday, Feb. 29.—Royal Institution, 3 p.m. Prof. Odling, "On the Chemistry of Alkalies and Alkali Manufacture."

Friday, March 1.—Royal College of Surgeons of England, 4 p.m. Prof. Flower, "On the Comparative Anatomy of the Organs of Digestion in the Vertebrata."

Irish Poor-Law Intelligence;

UNDER AUTHORITY OF THE

IRISH MEDICAL ASSOCIATION.

SLIGO UNION.

THE MEDICINES.

A LETTER was read from Messrs. Boileau, Boyd, and Co., medicine contractors, stating they had seen in the public press of Sligo, under the intelligence of the Sligo board meeting, particulars of a report lodged by Dr. Tucker, animadverting upon the quality of certain medicines supplied by their house to the Sligo dispensary. It was for the express purpose of making exception to Dr. Tucker's remarks that they now addressed this letter to the board, and they trusted the guardian's sense of justice would award them that consideration that a house of over one hundred and seventy years standing was entitled to. They wished to preface their remarks by stating that had there been any justifiable cause of complaint, it would have been more courteous to have apprised them, and thus given them an opportunity of explanation; but now it was made a public matter, and they should deal with it as such. Firstly, the contractors desired to state that, during the period they had had the honour of supplying the union, they never received a complaint of the quality of their medicines. Secondly, they denied that the medicines enumerated in Dr. Tucke'r report were bad, or inferior in any way; but that when they left their house they were of undoubted purity and best quality, and they called on Dr. Tucker to prove it otherwise. Further, they courted the most rigid inquiry into the matter, and requested that any of their drugs might be forwarded to the city analyst (he being the proper officer) for his report. Should his report prove contrary to the opinions of Drs. Tucker, Lynn, or Lougheed, they would expect that satisfaction afforded from one gentleman to another, and which they shall make use of as they thought fit and proper. Further, they beg to inform the board that, pending the decision and judgment of your board, we will bring the whole matter under the notice of the Poor-law Commissioners, and court their inquiry also; for they (the contractors) could not allow the matter to pass unnoticed, inasmuch as the respectability of their house was impugned, characterised as it has been for over a century and a-half as being distinguished for selling pure medicines. In Dr. Tucker's report he used the words "adulterated drugs." If he alludes to their medicines in this remark, they at once gave it a most unequivocal denial, and also stated that, as far as their house was concerned, their contracts to the many unions they supplied "was not a wholesale system of fraud on the sick poor." In conclusion, Dr. Tucker's report, in which he recommends the supply of medicines to be obtained from the Apothecaries' Hall, because they were legally bound to supply genuine medicines, they beg to inform the board and Dr. Tucker that they were bound by a much stronger tie than any legal form—viz., a character which they had endeavoured to maintain, and not without success, before the whole profession and the public, to whom they could appeal with the most perfect confidence.

The Clerk, in reply to a guardian, said that the medicines complained of were brought to the workhouse, and were then in the board-room.

Some guardians considered that the charge against the medicines was more for inferiority than for adulteration.

The clerk having produced Dr. Tucker's report and read it, the chairman said it appeared more an abstract charge of general inferiority and adulteration than anything else.

Mr. O'Connor would clear up all doubts on the subject by having the medicines analysed.

Mr. Walker and Mr. Barber were of the same opinion, and at their request the medicines were ordered to be laid before the board.

The master opened the different parcels, and they seemed to consist of a bottle of spirits of wine, a large bottle of cod liver oil, and parcels of valerian root. &c.

The Chairman remarked that the cod liver oil did not look very nice, but

Mr. L'Estrange, pointed out that the bottle had only a paper stopper, which he supposed was not the kind of cork sent by the contractor.

Resolved—That the drugs now returned by the Sligo dispensary committee be sealed with the union seal, and be forwarded to the city analyst for analysis and report, requesting him to state seriatim which of the articles forwarded appear to him to be of inferior quality, and that the Poor-law Commissioners be requested to sanction any charges attending this proceeding.

CASTLECOMER UNION.

THE VACANT OFFICE OF MEDICAL OFFICER OF THE WORKHOUSE.

IT was proposed and passed "that we strongly recommend the appointment of Drs. Sterling and O'Hanlon, the two dispenary medical officers of the Castlecomer dispensary district, to the favourable consideration of the Commissioners. We beg to submit for their more accurate information, the great advantages to be derived by the appointment of the two dispensary medical officers. 1st. The benefit of consultation in serious cases. 2nd. The undoubted advantages of mutual assistance in difficult operations. 3rd. The facility of obtaining immediate attendance in emergencies at the workhouse or hospital, which has been exemplified on more than one occasion by the Master of the workhouse having to procure the assistance of one of the dispensary medical officers. 4th. Heretofore, the medical attendance by Drs. Rosse and Carpenter gave the greatest satisfaction. We may add that the manner in which Drs. Sterling and O'Hanlon have performed their respective duties entitles them to the most favourable consideration of the Commissioners."

VOTE OF CONDOLENCE FOR THE LATE DR. NOLAN.

Proposed by R. Butler, Esq., J.P.; seconded by R. Cooke, Esq., J.P., and unanimously adopted:

"RESOLVED—That we feel deep and heartfelt regret for the death of Dr. Nolan, medical officer of the workhouse and hospitals of this Union. We deem it an act of justice to his memory to bear our testimony to the very zealous manner in which he discharged his professional duties, bringing to their performance high medical skill, kindness of manner, and above all, a conscientious anxiety for the sick poor committed to his care."

ENNISKILLEN UNION.

A CORRESPONDENCE was read—sent down by the Commissioners—in which Doctor Rogers asked advice regarding the course pursued by him in the case of a child named Terence Murphy, who, it appeared, was born in the Lisbellaw Union, and being subsequently removed to the Enniskillen Dispensary district, was successfully vaccinated by him in his capacity as Medical Officer of the latter district. The Commissioners stated, in reply, that so far as they were informed of the circumstances, Dr. Rogers appeared to have complied with the requirements of the third section of the Compulsory Vaccination Act. He might, it would appear, have sent a duplicate certificate to the Registrar of Births and Deaths of the Lisbellaw Dispensary district, in which the child was born, although such a proceeding was not obligatory on him.

Dr. Rogers said the magistrates in open court mentioned that he had not done his duty, and that an action might be taken against him—one of the same magistrates in the Enniskillen board-room expressed himself in the same manner. Mr. Sankey expressed himself very strongly, whereas he thought it was he who had best ground for an action. He thought it was harsh to fine the parent of the child in question.

◆

ENNISCORTHY DISPENSARY.

AT a meeting of the Committee of the Enniscorthy Dispensary, held here yesterday, Dr. Furlong of this town was appointed without opposition Medical Officer of that establishment.

DRUMQUIN DISPENSARY.

ELECTION OF MEDICAL OFFICERS.

A meeting of committee for the purpose of electing a medical officer for this district, in room of Dr. Joseph Todd, resigned, was held. Three candidates came forward—Dr. A. M'Master, Dr. George K. Given, and Dr. John Johnston. The voting in Omagh Union was in favour of Dr. M'Master, by a majority of three; and that in Castlederg was in favour of Dr. Johnston, by one. Dr. M'Master has been therefore elected for the Omagh, and Dr. Johnston for the Castlederg Union in this district.

Dr. Robert Saunderson, jun., youngest son of Dr. Saunderson, medical officer of Edenderry Dispensary, has been elected medical officer of Pettigo and Clonelly Dispensary Districts, in the Donegal and Irvinestown Unions.

STRADONE DISPENSARY.

A meeting of the Committee was held in Stradone for the purpose of electing a medical officer. There were two candidates—Dr. W. H. Parker, and Dr. James Matthews.

A poll was then taken, when there voted—

For Dr. Parker, 5; for Dr. Matthews, 6.

The Chairman declined to vote.

Dr. Matthews was declared elected.

THURLES UNION.

SUPPLY OF VACCINE LYMPH.

The Commissioners wrote acknowledging the receipt of the minutes of last meeting, containing a resolution of the Board, stating in reply to their letter of the 5th inst. that the Guardians do not subscribe for supplies of vaccine lymph for the several dispensaries of the Union. The Commissioners thought that the most satisfactory arrangement would be effected by the Guardians subscribing for each of the dispensaries as well as for the workhouse, as suggested by their circular letter of the 24th ult. The Commissioners would be glad to learn that the Guardians adopted that course.

ROSCREA UNION.

EMPLOYMENT OF DISPENSARY MIDWIVES IN THE WORKHOUSE.

Dr. Powell, the officer of the workhouse, informed the Guardians that he had to call in the dispensary midwife to attend a lying-in case during the week, and he wished to know if he would do so in future cases.

It was resolved in future, when necessary, Dr. Powell be empowered to employ the midwife at a remuneration of 5s. per case.

DUNSHAUGHLIN UNION.

The election of a medical officer for the workhouse took place last week. Two candidates offered themselves for the appointment, viz., Dr. Petit, of Dublin, and Dr. Laffan, of the Killeen dispensary district in the Dunshaughlin union.

On a division 19 voted for Dr. Petit, and 9 voted for Dr. Laffan. Dr. Petit was declared elected by a majority of 10.

The board unanimously passed a resolution testifying their high opinion of the eminent personal and professional qualifications of Dr. Connoll, late medical officer of the workhouse.

We commend to the attention of Poor-law Medical Officers the conduct of a relieving officer of the Galway Union, whose resignation was presented at the last meeting of the Board of Guardians.

The following conversation ensued.—

Mr. Redington—I would like to know Mr. Morris's reason for resigning.

Chairman—I would not like to lose a good officer without a reason.

Mr. Comins—But you are not to know his motives in sending in his resignation.

Chairman—Is it from ill health you resign?

Mr. Morris—No.

Chairman—And for what reason?

Mr. Morris—Well, I believe that if I did not resign now I would soon have to resign, from the feelings I see manifested.

Mr. O'Flaherty—Cannot you tell your reason?—I understand he got nineteen or twenty tickets the other day, and none of them required relief at all.

Mr. Fahy—I understand he is fully determined on resigning.

Mr. Martyn—I am only sorry that after Mr. Morris acting for us for nineteen years, we cannot now give him some superannuation,

Mr. Davis—I believe the reason for his resigning is, that a local warden in Spiddal sends him fifteen or twenty tickets nearly every day, while not a single one of those in whose favour they are issued require relief at all. He (Mr. Morris) consequently felt it better to resign than to endure persecution of this kind, or come to a quarrel with the party.

Mr. Comins—If that's the only reason he has, I would have him withdraw his resignation.

Mr. O'Flaherty—The wardens could be changed in Spiddal.

Query—How many Poor-law Medical Officers in Ireland would resign under similar circumstances? How many Boards of Guardians would care whether they did or not?

NEWMARKET-ON-FERGUS DISPENSARY.

The Commissioners forwarded to the Board a copy of observations appended by Dr. Frost to his report, Form L, relating to Newmarket Dispensary District.

Dr. Frost observed to the Commissioners that on his requisition to the Cow-pock Institution, vaccine lymph was supplied to him on two occasions; he took all due precautions to preserve it, yet of five children he vaccinated with it, not one showed any evidence of its having produced the usual vesicle.

The Commissioners stated, in reply to Dr. Frost, that he should represent the matter to the Board of Guardians with a view to obtaining a further supply. The Commissioners at the same time requested to be informed if Dr. Frost made use of Dr. Husband's capillary tubes as recommended by them, as a means of preserving the lymph, obtained from the children vaccinated by himself.

On Dr. Frost mentioning the matter to the Board, on the 31st January, they ordered the Clerk to send a copy of his observations to the Cow-pock Institution, which was done.

A letter was read by the Clerk from the Registrar-General stating, that in consequence of communications addressed to the Poor-law Commissioners, with a view to the more effectual carrying out of the provisions of the Compulsory Vaccination Act, the Clerk would permit the medical officer of the dispensary districts to inspect his registers of births, deaths, and marriages, in the months of June and December in each year, or at such other time, during office hours, as he may apply, in order that the names and addresses of parties whose children have not been vaccinated may be ascertained—ordered.

Quarterly Summary of the Mortality of Dublin.

Births.—In the Dublin District the number of births during the quarter amounted to 2,145, equal to 1 in 36, or 28 in every 1,000 of the population.

The number of births in the northern portion of the city was 890, or 1 in 30; and in the south, 856, or only 1 in 40 of the population.

There were *registered* in London during the same period 27,892 births, equal to 1 in 20, or 34 in every 1,000; in Glasgow 1 in 27, or 38 per 1,000; and in Edinburgh 1 in 30, or 33 in every 1,000.

Deaths.—The number of deaths in the Dublin District amounted to 2,164, or 1 in 36, or 28 in every 1,000.

The number of deaths north of the Liffey was 796, or 1 in 34 of the population; and south of the river, 1,041, or 1 in 33 of the population. In Rathmines, Donnybrook, Blackrock, and Kingstown, 1 in 50.

The deaths in Belfast represent 27 in every 1,000; in Cork the ratio represented by the number of deaths *registered* was 24 per 1,000; in Limerick it was 26 in every 1,000; in Galway 18 per 1,000; in Sligo 22 per 1,000, and in Londonderry 23 in every 1,000 of the population.

The number in London during the same period was 1 in 39; in Glasgow 1 in 33, and in Edinburgh 1 in 33.

Diseases.—Small-pox caused 176 deaths, or 1 in 12·3 of the total deaths. During the whole of the year 1870 there was no death from small-pox registered. The disease was imported from England. The following is the only information afforded by the returns as to vaccination:—33 persons were stated to have been vaccinated 57 not vaccinated; in 2 instances the observation was "vaccination indistinct;" in 2 "not known," and in the remaining 82 cases there was no reference to the subject. Thirty-four deaths of City patients took place in the North Dublin Union Small-pox Hospital, which is situated without the Dublin Registration District.

Bronchitis proved fatal in 333 instances, affording a ratio of 1 in 6·5 of all the deaths registered.

229 persons fell victims to phthisis, being 1 in 9·4 of the total deaths.

The assigned cause of death in 146 cases was convulsions.

One hundred deaths were caused by fever, viz.:—17 by typhus, 54 by typhoid or enteric, and 29 by simple continued fever.

Scarlet fever caused 60 deaths. In the corresponding quarter of 1870 177 persons died from this disease.

There were only four deaths from measles.

Twenty-five deaths were referred to whooping-cough, 17 to croup, 7 to diphtheria, and 3 to quinsy.

Diarrhœa caused 75 deaths, dysentery 4, and "simple cholera" 2.

Sixteen deaths resulted from erysipelas.

Ninety-two deaths were ascribed to heart disease, 9 to aneurism, and 4 to pericarditis.

Thirty deaths were attributed to mesenteric disease, 45 to hydrocephalus, and 13 to scrofula.

Cancer was the cause of 39 deaths.

Thirty-one deaths were ascribed to apoplexy, 30 to paralysis, and 6 to epilepsy.

Liver disease caused 32 deaths, nephria 10, and kidney disease (unspecified) 15.

STUDIES ON TOBACCO.

In the *Giornale Ven. d. Sc. Med.*, Dec., 1871, Prof. P. Mantegazza gives an excellent memoir on tobacco. He first speaks of the researches of Erlenmayer, who gives the following symptomatology of poisoning by nicotine. Conjunctivitis, diplopia, and amaurosis are not infrequent when tobacco is greatly made use of. The skin takes a yellowish hue, and furuncular eruptions are not rare. Stomatitis, glossitis, and black deposits on the tongue and teeth are noticed. Gastrodinia, mesenteric neuralgia, dyspepsia and feeble appetite are common, serous diarrhœa, and in severe cases, paralysis of the rectum. Pharyngeal catarrh, bronchitis, hæmoptysis, asthma, and catarrh are caused by smoking. The circulatory system presents palpitation of a special nature, with a certain anxiety. All authors agree that the genito-uninary organs are least affected by tobacco. The nervous system, in general, suffers a good deal from the chronic use of tobacco. Hyperæsthesia and neuralgia are common, and we have already seen that the optic and olfactory nerves are affected, whilst the nerves of general sensation are affected by various hallucinations. There may occur neuralgia of the various branches of the fifth pair, or of the ischiatic, or along the vertebral column. Anæsthesia is greatly pronounced over the whole skin, and especially on the legs. Analgesia also is complete. There is muscular weakness, greater or less, especially in the lower extremities, and sometimes so grave, that the patient cannot stand on his feet, and when seated must lean against a solid body. The horizontal position is the least grave. There also may be tremors in the limbs, uncertain gait, convulsive movements. Vertigo is an important symptom, which is conjoined with a sensation as if the eyes were continually rolling. The intellectual and moral functions are perturbed with a well-marked nervous irritability, with anxiety, with the terror provoked by frightful visions, with dulness of thought, melancholy, and timidity. In some cases there occurs true delirium accompanied by trembling, as in chronic alcoholism, in other cases there is profound melancholy, alternating with great exaltation, and with precordial anguish, and lastly, it may give rise to mania. Some observers have also noticed dementia.

Dr. D. Petrera made experiments on frogs with tobacco, and found the acceleration of the respiration first taking place to be followed very quickly by stoppage of respiration, stupor, palsy of the upper extremities, and congestion of all the viscera. Sichel speaks of amaurosis of tobacco smokers. Brodie accuses tobacco of injuring the race. Tiedemann speaks of the evils done to boys by smoking. Boys who smoke become weak, irritable, pallid, and thin. Cacopardo, of Rome, and Professor Scalzi, have spoken much against tobacco. They accuse nicotine of causing phthisis. Decaisne also says it lowers the intelligence of young men. King James in his work "rem turpem visu, olfactu insuavem, cerebro noxiam, pulmonibus damnosam," and adds that by means of tobacco "Corporis sanitas atteritur, res familiaris arroditur, dignitas gentis senescit domo, vilescit foris." (*Misocapnus*, 1644). Men have discovered in smoking a new pleasure, but also a new sorrow. And the race would have been far happier if it had never known tobacco. The evils of tobacco are—that it diminishes the general sensibility, and lowers public morality, makes the air in rooms unwholesome, takes men away from woman's society, sometimes produces severe poisoning, diminishes the working power of a people, and adds a heavy expense to the poor, and it shortens life, easily prompts to drinking, may cause amaurosis; it retards the growth of the young, causes nervous disease of all kinds, palpitation of the heart, asthma, weakens the will and the thought, and genital organs; weakens the digestive organs, and the whole organism and its muscles.—*The Doctor.*

LECTURES ON DERMATOLOGY.

Delivered in the Royal College of Surgeons of England, in February, 1872, by

ERASMUS WILSON, F.R.S.,

Professor of Dermatology to the Royal College of Surgeons of England.

LECTURE II.

Phlyctenous Affections.

THE *third* group of cutaneous diseases, the phlyctenous ffections, is represented in our collection by two examples f vesiculous lesion, namely, pemphigus and herpes. The xamples of pemphigus are numbered 109 to 119, with a ecent addition No. 518, and those of herpes 120 to 127. he lesions in the vesiculous form of cutaneous affections re three in number, namely,—erythema, vesicle or bulla, nd crust, and its pathological state is consequently morphic. If we analyse the pathological characters of affection, we shall discover it to be an erythema atded with serous effusion beneath the epidermis, the sed fluid raising the horny layer of the cuticle into a ter or bleb. It would be interesting to discuss why, in e cases, erythema should subside without leaving ind it any mark of its presence: Why, in other innces the erythema should be followed by dry exfoliation the cuticle; and, why, in a third series, as in the one ore us, it should be accompanied with vesication, and herpes, with suppuration and sometimes with ulceration ddition to vesication. An explanation ready to our d, and conforming with the existing theory of disease that the question is one of vital dynamics, and that changes referred to, represent degrees of vital or ners force. In ordinary erythema, the standard of nerve er or vital power is lowered to a certain degree, while phlyctenous erythema it is lowered still more, passively in the case of pemphigus, actively in the instance of herpes. After death, as we well know, a state of loosening and separation of the cuticle takes place, which is referrible to cadaveric transudation, and in some forms of cachexia, as well as in some of gangrene, for example in chilblain and carbuncle, the development of bullæ may be likened to a similar process.

The first specimen of pemphigus that we have to examine is *pemphigus iris*, a form of the disorder which supplies us with a curious example of the transition of erythema into the vesicular affection. Nos. 100 and 101, are instances of erythema iris, of a migratory form of erythema, in which the progression is centrifugal, and as it were saltatory, and the resulting consequence a singular eccentric arrangement of rings. But the eruption subsides without structural change and without disturbance of the epidermis. Not so, however, in pemphigus iris; the development of the central blotch, and the successive formation of eccentric rings are exactly the same, but another pathological feature is superadded, the central blotch vesicates, and becomes covered with a bulla or bleb. Sometimes the rings surrounding the central blotch also vesicate, and the curious phenomenon results of a central vesicle or bulla encircled by one and sometimes by several vesicated rings. The case ceases to be one of erythema iris, for the vesicle transforms it into one of pemphigus iris, and, as may be supposed, where a considerable number of eruptive spots are thrown out on the skin, some will retain the erythematous character, some will be bullæ with vesicated rings, and between these extremes, others will be found to represent every variety of intermediate stage.

An example of *pemphigus iris* is shown in the drawing No. 109, displaying the inner side of the thigh and leg of an adult man. In this case the eruption was general, but most abundant on the lower extremities; more frequently it is local and limited to the hands and feet. The outbreak is always associated with constitutional debility and irritability, and sometimes with cachexia, and in general there is more or less enteric disturbance, and a participation in the disease, of the mucous membrane as indicated by aphthæ, sometimes by uræmia, and sometimes by slight hæmorrhage from the alimentary canal.

The drawing illustrates very fairly the progressive stages of the eruption; its erythematous origin, the subsequent vesicle, the eccentric erythematous rings, the conversion of the more central rings into annular vesicles, the varied tints of the more distant rings; then the retrogressive stages, the opacity of the vesicle, its collapse, sometimes its rupture, the desiccation of the vesicle and its contents, and their consequent conversion into a thin brown scab. Occasionally the rings are each the production of a separate day, so that when the process has lasted for some time, it would be possible by counting the rings, to determine the day of appearance of the first spot and the number of days the patch had existed. In the large patch seen in the drawing, there are seven white rings, representing seven days, and seven circles of fading red between them, the outermost white ring being bounded by a narrow areola of pale crimson. While, in another patch, measuring only half-an-inch in diameter, there were nine different tints of colour, which, from the centre to the circumference, were—red brown, white, deep red, lighter red, deep red, pale red, deep red, yellowish white, and crimson blush.

Another very interesting illustration of pemphigus iris is shown in the model No. 518. The eruption in this case is seen in every stage of development, from slightly prominent red spots, little more than a line in breadth, to circular blotches, nearly three quarters of an inch wide. In the smallest spots there is redness merely, then follows a white vesicular centre with red margin; after that the central cuticular dome subsides, while around it an annular vesicle is produced, and this again is encircled by a red margin. Sometimes the central vesicle collapses incompletely, leaving a disc of white cuticle partly separated from the rete mucosum, in which case three rings may be distinguished encircling a central white disc, the colour of the rings being, firstly, a brown red, then one which is white, prominent, and vesicular, and thirdly a red halo. Upwards of fifty pocks in various stages are scattered over the surface of the hand, and in four places the vesicles have become abraded, and a brown exudation crust has been produced.

From the small size of the central vesicle, this form of eruption is sometimes but incorrectly denominated "herpes" iris, and the present model, on account of its vesicular centre, has received the name of "hydroa" in the Paris collection.

Pemphigus iris has been first selected in our description of pemphigus, because it occupies an intermediate place between erythema and phlyctena, and thereby forms a link between the typical erythema and the typical pemphigus. I may remind you that we have seen examples of eruption that seem to be the merest modification of erythema papulosum, but which assume the peculiar figure to which the term "iris" has been applied, and which, consequently, we have distinguished as erythema iris; nevertheless, another simple lesion, namely exudation, added to that already existing, is sufficient to convert erythema iris into pemphigus iris. Were it not for this transitional character, we might have treated pemphigus iris as the modification of an eruption, which is represented in a typical form by pemphigus vulgaris.

Pemphigus vulgaris is illustrated very fully in our collection by the series of drawings, casts, and models, numbered 110 to 119, which not only mark the physical appearance of the disease, namely, its hyperæmic origin, its vesication and retrograde progress, but also the constitutionally cachectic tendencies of the disease.

The patient, from whom the drawings 110 and 111 were made, was a strumous boy, 7 years of age; when three years old he received a blow on the knee, the injury produced swelling, and four years later the limb was condemned to amputation. With occasional intermissions, his life, up to the period of this report, was spent in hospital; and three years after, being invalided for his knee, the pemphigus made its appearance. The eruption was recurrent, lasting the first time for nine weeks, and subsequently for five weeks, with intervals ranging between ten days and two or three months. In all, he had six attacks, the eruption being chiefly developed on the limbs, and was much debilitated in constitution.

The plaster casts, Nos. 112 and 113, of the forearm of a child, display very strikingly the figure and bulk of the vesicles or rather blebs of pemphigus. Some of the bullæ are isolated, others confluent; near the wrist is a compound bleb of large size, formed by the blending of four bullæ, which were originally separate; whilst, in various places, others may be seen undergoing progressive retrogression.

The casts in wax and plaster, numbered 114, 115, and 116, representing part of the lumbar region and thigh of a young woman, aged 20, bear upon their face an evidence of the fatal cachexia, which constituted a part of her history. The skin is discoloured, almost swarthy, from the abundance of pigmentary deposit, the bullæ are small and imperfectly developed, some are in the state of collapse; dark brown stains indicate where others have subsided; and amid the rest, there are superficial ulcerations in various stages of healing, and deeply indented cicatrices. On the thigh, and within a small extent of surface, there are about eighty spots presenting every stage of progressive and retrogressive development.

As we usually meet with it, pemphigus is local in its development, limited to a part of the body, as the limbs; sometimes attacking the upper limbs, but more frequently the lower limbs. Occasionally, however, the eruption is general, as in the case of cachectic pemphigus already described, and in that from which the models, Nos. 117 and 118 were made. The patient in the latter instance was a female servant, aged 46, and the disease proved fatal in nine days, the affection being named by Guibout, *acute general pemphigus.* Although general, the bullæ were most abundant on the extremities, a few only being scattered over the face, upper part of the neck, and trunk; their average size was that of an almond, but some were much larger. Guibout notes that one day the bulla on the hand was a large, flat, uniformly elevated erythematous patch, bordered by a rose-coloured areola, and on the next became distended to its present dimensions. The young woman had a general appearance of health; she had been troubled for four months with nocturnal pruritus, beginning in the legs and thence extending to the whole body; for these symptoms she took baths and applied ointments, and the pemphigus followed immediately upon the use of an ointment containing turpentine. On admission into hospital she was suffering under enteric derangement, with a pulse of 112; three days later the tongue was coated, and the pulse 104; the next day the tongue was white; the day following the pulse was 100; there was much prostration, with delirium and a hot skin; the day afterwards she became comatose, the delirium continuing, and she died in the night without reaction. After death the chief internal morbid appearance was congestion of the mucous membrane of the small intestine.

The model No. 119, is another example of pemphigus, developed in this instance on the lower half of the right leg. Lailler terms it "acute pemphigus." Over a limited extent of surface are scattered nine bullæ, ranging in size between that of the hemisphere of a large pea and that of a large hazel nut; and about the same number of circular excoriations, caused by the rupture of other bullæ. The contents of the bullæ are semi-purulent and opaque, the distended bullæ are without areolæ, but the excoriations are surrounded by an erythematous desquamating border, within which is seen an edge of collapsed cuticle, and within the latter a thin brown scab. On one or two the scab is thicker, almost amounting to a crust; from others an ichorous sanguinolent discharge is seen to be issuing, and in two places there are clusters of three or four excoriations in which the erythematous borders and excoriated bases have become blended so as to form inflammatory blotches.

If, now, from our new point of view, we contemplate the groups of cutaneous disease which the present inquiry has brought under our notice—eczema, as representing common inflammation of the skin, revelling in almost every form of lesion of which the integument is capable, and erythema presenting the most elementary form of disorder, namely, simple hyperæmia, with or without disturbance of cell function—and advance towards phlyctenous affections in the instance of pemphigus with the curiosity and interest which attach to the question: What will cutaneous inflammation do next? What it will do and can do is now before us in the illustration of pemphigus; the hyperæmia or erythema of the skin will be rapidly succeeded by the effusion of an aqueous lymph over the whole surface, as if the latter had been subjected to the irritation of a blister; the erythematous base is circular in its figure, and the blister or bulla is equally round; if the erythematous base be small the blister will be correspondingly small, and if, as is very commonly the case, the erythematous blotch increase by its circumference, the blister will likewise increase until it arrive at the very edge of the erythematous base, and attain a magnitude of very considerable extent. And this is one of the peculiarities of pemphigus, that the blister appears to arise from the unaffected skin, often without a trace of areola or without any margin of hyperæmia around its circumference. In the models before us, we have blisters of very considerable size, but we occasionally hear of their reaching the bulk of an egg, of an orange, and even a greater magnitude.

We may realise the idea of pemphigus by a word, such for example as *idiopathic blister* or spontaneous blister, and just as we know the effect of a blister of cantharides, or of a jet of boiling fluid, or of a flame of fire, to be at first redness, and then a blister; so, in pemphigus, we see the blister rising spontaneously without either epispastic, or scald or burn. We may, however, very reasonably infer that, although there has been no irritant applied, yet that a similar change has taken place in the skin; and, as we know that the effect of these irritants is to lower the vital dynamics of the skin; so must we, in the absence of any external agent, arrive at the conclusion that some cause capable of reducing the vital force of the skin is present in the organism; and, furthermore, that such cause being the agent of a lowering of the vitality of a part of the body, approaching to a partial death of the skin, will be a matter of serious portent to the life of the individual. The conclusion is inevitable, pemphigus is a grave and serious affection, an associate of cachexia, always a symptom of a depressed vitality of the organism, and not infrequently a sign of a fatal state of disorder of the economy. The whole of the cases that we have examined are suggestive of a grave, and frequently fatal derangement of the organisation, and those which follow corroborate this anticipation.

In pemphigus we have the opportunity of noting certain phenomena resulting from the nature of the exudation which, however simple in themselves, are nevertheless worthy of our observation. The exuded fluid which, in its qualities, corresponds with the serum of the blood, is at first perfectly transparent, but gradually becomes opalescent, and at a later period is more or less distinctly yellow from the development of pus globules. In its transparent state it displays like an optical lens the congested base upon which it has arisen, and enables us to observe that the base is one while crimson, and another while purplish in its hues; but as opalescence sets in, this feature of the eruption is lost. A similar observation becomes a mark of diagnosis in the instance of the minutest of the phlyctenæ, that which, from its millet-seed size, is termed miliaria. The cuticle in miliaria is remarkable for its tenuity, its little rounded vesicles resemble beads of sweat upon the skin; hence, its cognomen, sudamina, and the one while transparency that transmits the red colour of its base, and another while opalescence that recals the appearance of drops of milk, have gained for it the distinctive appellations of miliaria rubra and miliaria alba. These appearances are well illustrated by the models on the table, and I beg to call particular attention to the model 117, with respect to which it is especially noted by Guibout that the large bulla on the back of the hand, measuring about three inches square, was one day a large, flat, uniformly, but very slightly elevated blotch, bordered by a rose-coloured areola, in fact, an erythema, and the next day the enormous vesication that we now see before us.

The transparency, the bright colour, and the benignant purulency of the bullæ of pemphigus, are always grateful to our eye as being of good augury, and teeming with hopeful expectation. But the purplish, and purple, and leaden-coloured tints, are less satisfactory. Sometimes the fluid of the blisters is reddened or empurpled by admixture with blood, which may be the result either of accidental pressure or friction, or the consequence of hæmatolysis, which betokens a state of cachexia in a more or less advanced degree. We are all familiar with the ugly, flat, leaden-coloured bleb of a devitalised chilblain; or the sanguineous bleb of a carbuncle, or the equally ill-conditioned bleb of a cachectic rupia; these are so many examples which find a comparative illustration in pemphigus, when it occurs in a cachectic constitution.

Another point of interest that attaches to the history of pemphigus is the mode of retrogression of the bleb. The more natural course of the retrograde change would be the gradual collapse of the vesicle; it becomes wrinkled, it contracts, it subsides, it falls down upon the surface from which it arose; it dries up into a thin scab which covers the base for awhile, being kept in its situation by the agglutination of its inspissated contents, and finally it drops off in the shape of a thin flat scale, when the base upon which it rested has healed and has become reinvested with normal epidermis. I am describing the most favourable course of retrogression of a pemphigus, one which presents the least possible departure from the standard of health, in fact the history of the healing process of a common blister, but you will perceive at once how a variety of small accidents may alter the harmonious working of the curative operation. The bleb may be accidentally bruised or broken or displaced, and then the covering of the inflamed skin will be a crust resulting from the exudation of inflammatory products. Or an exudation of inflammatory products may accompany the ordinary mode of healing by evaporation, and the scab may attain considerable thickness. Sometimes, also, in a state of low vitality at the cutaneous tissues, there may occur superficial gangrene and sloughing, succeeded by ulceration.

The French dermatologists have described a form of pemphigus which they denominate *pemphigus foliaceus;* the disease itself is of the low and cachectic type, the eruption is serpiginous in its character, creeping outwards upon the neighbouring skin; the contents of the bullæ are aqueous and non-plastic, and the cuticular dome of the bulla falling into wrinkles as it descends upon the inflamed base, and drying into a thin greyish and tawny scab, has suggested the idea of a dried leaf and the corresponding designation of the form of the eruption with which it is identified, that of "pemphigus foliaceus."

I may also mention in this place and as a note for future comment, that I have seen pemphigus in association with scabies, and also with prurigo. In these instances the blisters were the consequence of a neurosis, and this explanation will help us to understand the nature of some cases of local pemphigus which are rare, but which have been described under the name of pompholyx.

Another *phlyctena* of smaller dimensions than the *phlyctis* of pemphigus, but one of an interesting and important character has been termed herpes, and herpes is illustrated in our collection by a series of specimens beginning with No. 120 and extending to 127.

It is no part of my intention or wish to disturb the signification of a term which was settled by Willan, and has been accepted by all dermatologists since the days of our distinguished countryman; but it is a habit with me and one beyond my control, to endeavour to search out the meaning of the words which I am required to employ, believing most faithfully that where those terms have decended from medical philosophers of such acknowledged greatness as our ancient masters, Æsculapius and Hippocrates, they must embody some intelligible signification. Passing in review the various terms that I have had occasion to use hitherto in the course of these lectures, namely, eczema, psoriasis, pityriasis, scabies, lichen, impetigo, erythema, urticaria, pemphigus, and herpes, I find two instances in which I would put in a firm protest against the nomenclature adopted, one of these being lichen, and the other herpes. The term lichen has been settled by Willan to signify an eruption of pimples, but the real meaning of the term is made manifest when we trace back its derivation to the word λειχειγ, lingere, to lick, as though it were intended to refer to a something which adhered to the surface as the tongue in licking adheres to a plate of glass. The illustration is perfect in the instance of the growth of a vegetable lichen on the bark of a tree, while nothing can be conceived more opposite to the genius of the word than a mere crop of pimples, the "papulæ" of Celsus.

My other exception is taken with regard to herpes. Herpes, as settled by Willan, is made to signify an eruption of vesicles. But herpes is derived from ερπειν, serpere, to creep, from which we obtain the adjective serpiginous or creeping. Now herpes, as we at present understand the use of the term, is no more a creeping or serpiginous form of eruption than is erythema or eczema, both of which present themselves occasionally in the act of obeying a pathological law of the skin, namely, that of creeping onwards by the circumference into the neighbouring skin, whether at the same time they heal within the area or not. The true herpes was denominated "serpigo" by the Latins and the synonymous terms herpes esthiomenos, and herpes exedens, both occasionally crop up as the accustomed designation of lupus, epithelioma and dermatosyphilis.

I feel, Sir, that observations of this kind cannot be out of place when addressed to a body of scientific men whose daily bread is the harvest of learning, and who are always foremost in the bands of those who seek to improve and elevate the intellectual nature of man. As a teacher, I should hardly be doing my duty were I not to endeavour to explain, as I went on, the technicalities which have been imported into a subject so closely identified with medicine and surgery as dermatology. While in the class room it is an obvious necessity to be prepared to satisfy the eager questions of those who have a claim to all the information we can bestow, and with whom the demands of *wherefore* and *why* are very reasonably of constant occurrence.

◆

ENURESIS:

ITS CAUSES AND TREATMENT.

A CLINICAL LECTURE DELIVERED AT THE LONDON HOSPITAL.

By Dr. Bathurst Woodman,

Assistant-Physician to the London Hospital, and Physician to the North Eastern Hospital for Children.

(*Continued from* p. 183.)

There was a boy James L., æt. 4½, brought to me with enuresis, whose mother gave me such an account of his symptoms, that I asked Mr. Tay to examine him, without myself inquiring, as I perhaps should have done, more minutely into the case. Mr. Tay sounded the bladder, and finding no stone, referred him back to me. I got the mother to bring me some of the water, and found it *loaded with lithates*, and *extremely acid*, and on standing, there was a copious deposit of *crystals* of *uric acid*, and also of *oxalate of lime*. Some of these were very large, and in fact minute calculi. Free use of diluents, a regulated diet, and the tincture of perchloride of iron in 5 minim doses soon relieved him. He also had warm baths to make his skin act, and to promote absorption of fluid.

An older boy, came about the same time, whose age was about 9 years. He had had a very severe attack of scarlatina, followed by dropsy, when 2 years old. But the present affection dated from the beginning of the autumn which was somewhat wet and cold.

No cause could be ascertained, till I examined the urine, when I found it contained *albumen*. On treating him for this, and enjoining avoidance of cold and damp, and the wearing of flannel, I had the gratification of finding him quickly cured of this troublesome symptom.

A girl, æt. 8, was brought to me with incontinence. On inquiry we found she had *worms*, both lumbrici and oxyurides When these were expelled, the incontinence was cured, without any further treatment being necessary. Probably, the thread-worms irritated the rectum, and perhaps crawled up the vagina, as they often do, and thus excited the reflex act of micturition. To prove to you that this is often a reflex act, I may remind you that old nurses often *tickle* the inside of the thighs to make a child pass water, and that carters do the same to horses as well as whistling to them!

A girl of 12, the subject of hereditary syphilis, was brought to the Children's Hospital for incontinence of urine. She had been taking tonics, and belladonna, and syrup of iodide of iron, for weeks, and had been severely chastised, but the bed and child both continued to suffer. Examination proved that there were mucous tubercles about the anus, and the fourchette. These cured, the incontinence vanished. I might tell you of other cases, where sugar in the urine, where very ammoniacal and phosphatic urine, from catarrh of the bladder, or where effects of fear (waking up from a frightful dream), or fissure of the anus, or piles (though these are rare in children), or polypus of the rectum, appeared to be the exciting causes; but I will only give you two more. One is very interesting, although incomplete, as I lost sight of him, and my notes are imperfect.

A boy, æt. 10, had a stab in the back, in the median line, between the 11th and 12th dorsal vertebræ. There was not much bleeding, and at the time he had no very bad symptoms. Eighteen months after this, he had incontinence of urine come on, but there seemed no paraplegia, neither was there anæsthesia of the lower limbs. I could find, however, no other cause for this symptom. With rest, good diet, and perchloride of iron he improved a good deal, but I lost sight of the case, and cannot say whether he was cured.

The other patient was a young lady of 19, who was engaged to be married, but dared not, of course, until cured of her enuresis. Examination disclosed a vascular tumour of the meatus urinarius. It was snipped off, and in about three weeks she was not only cured, but married!

As I hold that a clinical lecture should not be too long, I shall just mention a few of the other causes, which one sometimes meets with. When I say paralysis of the bladder is *seldom* a cause, I doubt not that there are cases in which it is so, or at least of those muscles which act as sphincters. This was probably the case in the boy who was stabbed. It is so in some cases of paraplegia with incontinence. It is so when the urine has been *retained* too long. But *spasm* of the bladder may also be a cause, and doubtless is so sometimes in epileptic, and so called hysterical cases, when combined with relaxation of the sphircters. In obscure cases, *inquire if there be epilepsy in the family, if the child have had or has fits.* Let it be watched at night, and look yourself for minute hæmerrhages in the neck, and about the back of the shoulders, and for marks of bruising, or of tongue-biting. Remember that *chorea* of the bladder is not impossible. Keep calculi, and abnormalities of the urine in mind, ascertain whether the patient masturbates. Do not forget the possibility of disease of the kidneys, bladder, or rectum. Above all things, do not overlook the existence of obvious causes of irritation about the external genitals. Bear in mind that night-terrors may be due to lead-poisoning, and that this may perhaps cause incontinence. Ascertain the presence or absence of spinal or cerebral disease. In short *study every case by itself*, in the light of other cases, and your treatment, which must needs be as varied as the causes, will generally be successful. As some *method* is desirable, I would recommend the following :—

1st.—Inquire carefully into the duration, and frequency of the incontinence, and into the previous history of the child, and the family.

2nd.—Carefully note the diathesis, and general bodily condition of the patient.

3rd.—Examine the *urine* by test papers, by other tests, and by the microscope if necessary.

4th.—Make a careful examination of your little patient, including the anus and rectum amongst the pudenda, and if needs be, exploring the bladder also. I need not enjoin upon you all possible delicacy and tenderness in these examinations. You must explain the necessity to the parents —and you will often astonish them by evidences of neglect of cleanliness, or of the existence of sores of which they were ignorant.

5th and lastly.—Suit your treatment to the case ; removing or soothing all causes of irritation, and at the same time endeavouring to improve the general health, for it is quite true that delicate and tubercular children, or those weakened by long and severe illnesses, such as the exanthemata, suffer most. Above all things *do not countenance corporal punishment for this* bodily infirmity. It is as cruel, as it is usually useless ; and I am in the habit of saying, that the parents or nurses ought to be beaten, and not the little patients.

I will mention two or three *auxiliaries* to treatment, useful in a great number of cases.

There is first the warm-bath ; a sitting-bath is all that is generally needed. It should not be *too* warm, indeed 90° or at all events 98° is quite warm enough. Next, I have found it of great service to forbid the little patients to drink anything after their tea (say at five or six o'clock), unless thirst be extremely pressing.

On the importance of *waking* them up once, twice or more in the night, to make water, I need not dwell. This is not so cruel as it seems, the child is soon asleep again in most cases. It is also well not to let them lie on the back. The trigone of the bladder is the most sensitive part, and besides, it is possible the posterior regions of the spinal cord get unduly congested. A reel (such as used for cotton), fixed in the middle of the back sometimes prevents this, and the child may be turned over on the side. For local sores, the glycerine of tannin, aided by cleanliness is very valuable. I wish it did not stain the sheets so much. As tonics, mineral acids with bark, and the perchloride of iron, are the best I know ; and if sweetened, children seldom refuse to take them, which is a great advantage.

As a sedative, belladonna is, perhaps, often better than opium. You may give from one-eighth to one-fourth of a grain of the extract even to very young children, three or four times a day. This is the most successful empirical remedy I know, and in obscure cases, always deserves a trial, increasing the dose within the limits of safety. Should the urine, however, be saccharine, ammoniacal, or phosphatic, opium must have the preference. For ascarides you will use local injections. Salt and water enemata are as good as anything else. In epileptic cases, cod-liver oil (if the fits are tubercular in origin) will perhaps deserve to be considered as more than an auxiliary.

It has been well said that " La Médecine guérit quelquefois, soulage souvent, console toujours," but, gentlemen, if you act thus, if your treatment be scientific, which means, founded on knowledge ; there are few cases you will not be able to cure, fewer still you cannot relieve and none at all you may not console.

ON THE TREATMENT OF ECZEMA.

By J. L. Milton,

Surgeon to St. John's Hospital for Skin Diseases.

(*Continued.*)

Exercise.—After counselling the patient to protect the skin as far as possible from the air, it may seem a contradiction to recommend plenty of out-of-door exercise, but trial will show that they are quite compatible. All things that irritate the skin should be kept from it, and the air does irritate it. The most successful local treatment seems to be that which most effectually wards off the air, and I suspect that the efficacy of the nitrate of mercury ointment is due, not to any curative power it possesses, but to the fact that the nitric acid combines with the albumen of the serum and epidermis so as to form a crust, an almost impermeable obstacle to the action of the atmosphere. Too much light is almost as injurious, and I have often traced relapses to long exposure to the sun, or to the east winds on very bright days. Indeed, in some very severe cases, until a certain progress has been made towards recovery, the best plan would probably be to shut patients up in a dark room. But cases which require such stringent measures are the exceptions, and in general the patient is all the better for plenty of fresh air and exercise. As a rule, I have no faith in any system of treatment which compels people to stay in the house. M. Rayer says (*a*) that he has met with "several cases of eczema in which a vast variety of therapeutic agents had been fruitlessly employed whilst the patients went on with their usual occupations and took active exercise, but which were successfully effected by the same means from the minute these individuals consented to lay themselves up." This may now and then happen with patients who are unable to procure a sufficient supply of wholesome food ; who sleep in close overcrowded stinking bedrooms ; who have to stand a great deal and face all weathers, or who lead a very hard anxious or wearying life, but I have never seen an instance in which I could trace the incurability of eczema to such causes as exercise only.

Again, great exhaustion may militate against the patient taking much exercise, especially in the shape of walking, which is not a desirable method when there is any great weakness or when it is carried to the extent of inducing fatigue. Apart from these exceptions I always advise as much of it as I can, especially in the shape of boating, cricketing, riding, &c.

Diet.—As to diet all that ever I have observed points to one conclusion, namely, that eczema is another word for exhaustion. It occurs to a great extent among those who work too much and use an innutritious diet, or in whom mal-assimilation is going on. In some persons it seems to be almost a necessary result of an improper mode of living and overtaxed energy. Great anxiety, which is so potent and prevalent an agent in the development of this malady almost certainly entails some degree of exhaustion. I have often found that patients suffering from eczema, as indeed from many other forms of exhaustion, either owing to want of appetite for plain wholesome food or to want of means, go day after day without dining, living on tea or coffee and bread and butter, or bacon, bloaters, sausages, or something of that kind "as a relish." One of the worst cases of eczema I ever saw was in a gentleman who boasted that he never dined. He took six or seven cups a day of strong coffee and the sort of diet I have mentioned ; long before he was rid of his tormentor he was satisfied that he had been making a mistake. In some few cases this complaint may be brought out or kept up by the over free use

---

(*a*) "A Therapeutical and Practical Treatise," &c. By P. Rayer, M.D. 1835. P. 302.

of stimulants; but it prevails very extensively among temperate persons and total abstainers; and in children, among whom it is seen to such an extent, stimulants can have nothing to do with its appearance. Occasionally it seems to come on from the want of fresh vegetables, and wears much the appearance of scurvy (for which it is frequently mistaken by patients), being marked by great loss of strength, soft spongy state of the gums, indented tongue, foul breath, tendency to bleeding from the mucous membranes, costiveness, coldness, and coarse muddy look of the face, often with great dejection of spirits.

I have always found that a good plain diet, containing a fair amount of meat, say half a pound a day for an adult, with a large proportion of fat, an item only too often omitted or objected to by patients, with plenty of well boiled vegetables, fat ham or bacon and eggs for breakfast and some good red wine, was prescribed for eczematous persons. The patient should eat only brown or household bread, the white bread commonly sold containing scarcely any nutrient matter. Fat bacon fried, boiled eggs and brown bread form, perhaps, the most nourishing and digestible diet that could ever be put upon the table. After numerous trials, in which I have been very kindly assisted, I am disposed to say, with little, if any qualification, that in eczema red wine is superior to any kind of beer or spirits, and that the best kinds I have tried are tarragona and claret. As in pityriasis the latter answers extremely well in hot weather. A grown person suffering from eczema may take three or four glasses of tarragona a day, and even children bear a glass daily very well, especially if made into negus. When the weather is neither very hot nor very cold, two glasses of tarragona and four of claret, mixed together, make a very useful and pleasant substitute for either separately. In the case of women who are suckling, stout may sometimes be given, but it never answers so well. When the scorbutic symptoms just spoken of are prevalent, pure lemon-juice becomes invaluable; and it is a singular fact, that no remedy which I have tried relieves the sensibility to cold, often noticed in eczema, so quickly as lemon-juice; but only the freshly squeezed juice should be employed; that sold in the bottle by fruiterers and confectioners cannot be relied on. The same effect from lemon-juice has been noticed in the cold stage of ague.

From starving, bleeding, and purging, men have gone to the other extremes. Fat meat, cod-liver oil, bran biscuits, five or six glasses of wine daily, stout to dinner, rum and milk first thing in the morning, hot milk and beef tea between breakfast and lunch, and even food during the night are now given to patients who, a few years since, would have been restricted to gruel and tea, dry toast and barley water, with just about as much solid food as would keep a baby alive; a diet much more calculated to hasten the passage of the spirit to another world than to support the frame and the devastating action of calomel, antimony and black draught—bleeding and leeches. In skin diseases at any rate, extremes meet, and at a point where they do mischief, the high feeding of the present day is as hurtful as starvation was. It might, in rare cases, be put in requisition for a few days with the view of relieving great exhaustion, but as a system it does not answer. Too much animal food is especially injurious in eczema. We do not know very much about the action of food, but this much is well known; for it is an established fact, that however good may be the meat on which soldiers and sailors are fed, if they get too much of it and too little vegetables, they fall into a state of purpura, frequently accompanied by eczema and certainly akin to it; both blood and tissues being in such a state that a slight blow will blacken a whole limb. In training for prizefights, the men are fed on a diet composed almost exclusively of bread and meal, and for a time seem to get into extremely high health on it; but in a very well-informed paper (*All the Year Round*) it was stated, some few years ago, that the health of these men rapidly break down after a few trainings, and that an unusual proportion of them are cut off by dropsy and consumption, to an extent which the supposed looseness of their lives will not altogether account for. On the other hand, the better the feeding, so long as it is well digested, the healthier the skin; starvation makes it coarse, flabby, and offensive to the smell. Hufeland mentions (*a*) that a lunatic, who wanted to starve himself to death, exhaled a most noisome smell from his skin so soon as the starvation began to tell upon his health. To a certain extent I can confirm this. Not only have I observed that the skin is, on the whole, more offensive in the underfed, even when cleanly, but I have notes of six or seven cases where, to my surprise, I had remarked that persons, whom I had known in better circumstances, and in whom I had then never noticed it, had acquired during poverty a very unmistakeable odour. Again, more nourishing food was introduced at an insane asylum where skin diseases had previously been very common. Cocoa was substituted for gruel, meat for soup, wine was given to the feeble. The result of this was that diseases of the skin became rare indeed, to use the words of the physician who communicated the fact (*b*). At the same time, I cannot say that those observations are sufficiently complete to warrant me in drawing any particular conclusions. They point to some fact, but nothing more.

In acute eczema, or in sudden and severe relapses, a light diet such as chicken, rabbit, ham, veal broth, with fish, as soles and whiting for instance, and farinaceous food, is often advisable for a few days. Again, I have often seen people worse after indulging too freely in pork, curries, or strong soup, and patients frequently notice the fact.

Mr. Wilson does not fear any ill effects from the use of salt meats; he thinks it is bad reasoning to argue, that because soldiers and sailors suffer from scurvy, owing to their being so much fed on junk, therefore salt meats, which are fresh and sweet compared with junk, are likely to bring on scurvy. A monotonous diet, he thinks, injurious; as does Mr. Hunt, who holds that so long as there is plenty of change, it is of little moment what people eat, and that half the skin diseases under which children at boarding schools suffer owe their existence to the sickening monotony and the restraint. As a change, salt meat occasionally, especially such salt meat as good fat bacon or boiled ham can do no harm, at least I never saw any; but the frequent use of salt meat out of which the juice has soaked, and the fibre of which has perished and become saturated with salt and nitrate of potass, cannot fail to be productive of mischief. The patient just spoken of took no meat except of this kind. Mr. Wilson looks with little favour on salads, potatoes, and watercresses; salads he thinks, can only be made tolerable by adding oil to them, and watercresses have merely their pungency to redeem them. On the other hand, Dr. Edward Smith (*c*) and Sir Thomas Watson consider potatoes as a very valuable article of food.

(*To be continued.*)

◆

Death of a Medical Student from Chloroform.—The coroner for West Middlesex held an inquiry on Friday last, touching the death of Mr. Mark Furnivall, aged 22 years, a medical student. Mr. O'Hagan, a solicitor's clerk, said that he had known the deceased for some time past, and he last saw him alive shortly after midnight on Monday at the Arundel Hotel, Strand. Between nine and ten o'clock on Tuesday morning witness was called into his room, and found him lying dead in bed. Witness had heard that he suffered from heart disease and was in the habit of putting chloroform on his handkerchief when he went to bed to allay pain. When he was discovered dead in bed he had the handkerchief to his nose and mouth. Witness had no reason to believe that he would commit self-destruction. He was quite sober when he went to bed, and appeared very cheerful. Dr. Dunn, M.R.C.S., said that the *post-mortem* showed death had resulted from inhalation of chloroform. Verdict—Accidental Death.

SPECIAL REPORT ON FOODS,

INCLUDING DIFFERENT KINDS OF

FARINACEOUS PREPARATIONS FOR INFANTS AND INVALIDS,

MEAT EXTRACTS, AUSTRALIAN MEATS, &c.,

Together with reliable Chemical Analyses by Competent Professors.

[PREPARED EXPRESSLY FOR THE "MEDICAL PRESS AND CIRCULAR."]

No. I.

PRELIMINARY REMARKS ON THE PHYSIOLOGY OF FOOD.

There is no subject of greater moment to the individual, or to the community at large, than that of food. We do not think we can be accused of exaggeration when we aver that national prosperity in great measure depends on the proper supply of fit and unadulterated food.

Notwithstanding that of late years great advances have been made in attaining to a knowledge of the nutritive values and special functions of the various principles of food, we believe that there is still a wide field open for investigation.

Before proceeding to lay before our readers our series of analyses of the more important artificial foods we deem it advisable to take a brief survey of the modern views as to the physiology of diet.

Various classifications of foods have been proposed from time to time, it is not so very long ago that the division of alimentary materials into *nitrogenous* and *non-nitrogenous* was promulgated by the illustrious Liebig, and almost universally adopted. We can see no objection to this classification as we have stated it, but when we are told that the term *nitrogenous* is to be considered as synonymous with "plastic," or "histogenetic," or "nutritive," and the term *non-nitrogenous* with "respiratory," or "calorifacient," or "heat-forming," the classification is no longer admissible. Probably the best classification, as involving no transitory theory, is that of Dr. Prout which indicates the necessity of four classes of principles of food —viz. :—

1. Albuminous.
2. Oleaginous.
3. Saccharine and Amylaceous.
4. Inorganic.

The most recent experimental researches have been confirmatory of the view that a food competent *permanently* to nourish, to renovate, and to support, must have a representative of each of these principles in proportions varying with age, sex, idiosyncracy, habit, or occupation, race, climate, &c.

We shall hereafter allude to the function which each of these principles subserve in the organism.

Physiologists and chemists have long sought to establish a *nutritive standard* which would serve as a basis for the determination of the nutritive values of foods. For the reason that the requisite quantity and quality of foods depends on the modifying influences above mentioned any attempt to establish an *universal* nutritive standard must fail. The blood has been adopted as a standard, but when we reflect that blood, while it is doubtless the proximate medium of nutrition is *also the vehicle of disintegrated products* we have said enough to show that the blood cannot be regarded as a reliable criterion. Milk also has been selected as a standard. Now milk is a model food for infancy, and although a man would live better on bread and water than on milk alone, still, we must allow that the latter affords a valuable *general approximative* standard. A nutritive standard, in fact, will vary for almost every individual, and can only be ascertained by the test of experience in each case.

We now pass on to consider the relative value of the nitrogenised and non-nitrogenised principles of food. It was part of Liebig's theory that the development of motive power was the prerogative of nitrogenised food. This view is no longer tenable, recent researches having proved indubitably that development of force and nutritive function are the attributes of the non-azotised as well as the nitrogenised aliments, and that, on the other hand, the nitrogenised principles are calorifacient as well as plastic. While it is true then that both nitrogenised and non-nitrogenised principles are factors of force we would here direct attention to the fact that "the muscular qualities of the two kinds of food differ considerably from each other." The Rev. Prof. Haughton in his eloquent address at the Oxford meeting of the British Medical Association in 1868, after illustrating this fact by a reference to the comparative muscular powers of cats and ruminants says, "we find among ourselves an instinctive preference given to farinaceous and fatty foods, or to nitrogenised foods, according as our occupations require a steady, long-continued slow labour or the exercise of sudden bursts of muscular labour continued for short periods.

Not only has it been demonstrated that nitrogenous diet is not essential for the sustentation of labour but it has also been proved that the quantity of the urea excretion is always proportionate to the quantity of nitrogenised food ingested, but bears no relation to the dynamical actions of the body. These facts are wholly at variance with Liebig's view that dynamical force is the result of *tissue combustion*, and not of *oxidation of food.* We may here allude to the beautiful experiments of Professors Fick and Wislicenus (*a*) which, supplemented as they were by the accurate researches of Professor Frankland (*b*), and more recently by those of Professor Parkes (*c*), prove beyond all doubt not only that hard work may be done on a non-nitrogenised diet, but, moreover, that exercise causes no appreciable increase of nitrogen in the urine, that, on the contrary, the quantity of urea excreted during rest is in excess of that eliminated during active work. We have not space to enter more minutely into this subject but will refer our readers for details to the writings of the authorities we have quoted. We believe that the warrantable conclusion to be drawn from these researches is that oxidation of the hydrocarbonaceous foods developes *heat* which is convertible by the muscles into *mechanical force.* We are not yet absolutely prepared to concede that the motive power of a food depends on its thermotic attributes, but modern research, we must allow, tends to this conclusion. Now we must not be supposed to depreciate the

(*c*) *Ibid,* 1867.

value of nitrogenised food. The experiments of Dr. Parkes prove indubitably that deprivation of azotised food during sustained active labour results in physical exhaustion and structural impairment of tissue. The question now presents itself, what are the chief functions of nitrogenous foods? They are first and chiefly the construction and reparation of tissue; that they subserve the respiratory function and aid in the development of mechanical force is undoubted, and, lastly, that they aid in the assimilation of the hydrocarbons is at least probable. With reference to the latter functions there are many matters yet requiring elucidation.

Of the non-nitrogenous principles of food the oleaginous group differ from the saccharine and amylaceous in being more potent as respiratory and calorifacient agents. The importance of a due proportionate supply of oleaginous matter in a diet cannot be too highly estimated. Lehman claims for fat an active agency in the digestion and metamorphosis of animal matter. Fat unquestionably is an active agent in tissue-fabrication and no less certainly does it aid in the normal process of structural disintegration. What are its functions in nervous matter in which it exists so abundantly we cannot confidently affirm, but that they are important is undeniable. It is needless to refer to the mechanical functions which fat performs in the body.

The saccharine and amylaceous articles of food although of great value in other respects possess scarcely half the calorific power of fat. That starch and sugar subserve the production of fat we believe has been experimentally determined.

One of the chief functions of this group of alimentary principles we believe to be their conversion into the various organic acid compounds such as lactic acid, butyric acid, &c. We cannot yet positively define the exact function which these acids perform in the organism, but it is reasonable to attribute to lactic acid the office of aiding in the digestion of azotised matter, and in the words of Dr. Letheby "perhaps its occurrence in the juice of flesh is for a similar object, namely, the solution of effete tissues" (*a*).

We have not space to enter here into the subject of the alimentary value and functions of the saline constituents of food. The universal presence of them throughout the body, the craving which the system experiences on deprivation of them and the deviation from health consequent thereon prove that they are of essential value. Dr. Letheby says, "the saline or mineral constituents of food are largely concerned in the metamorphosis of matter, and perhaps this is their sole function, for it is a speciality of these substances to give a valuable form to the plastic constituents of food and of the animal tissues."

◆

At a special meeting of the Council of the Royal College of Surgeons, on Thursday last, Mr. Henry Spencer Smith, F.R.C.S., a member of the Council of the College, and Senior-Surgeon to St. Mary's Hbs-Hospital, was elected a member of the Court of Examiners for a period of five years, in the room of Mr. Cock, consulting-surgeon to Guy's Hospital, whose term of office had expired.

(*a*) "On Food: being the substance of four Cantor Lectures delivered before the Society for the Encouragement of Arts, Manufactures, and Commerce." By H. Letheby, M.B., M.A., Ph. D., &c., Professor of Chemistry in the College of the London Hospital, and Food Analyst for the City of London. London: Baillière, Tindall, and Cox.

Transactions of Societies.

SURGICAL SOCIETY OF IRELAND.

The Society met on Friday Evening, the 16th ult., at the Royal College of Surgeons. The President of the College, Mr. Wharton, in the Chair.

Dr. Pratt read the following paper

ON THE ORIGIN OF FEVER.

Mr. President, I own it is a difficulty with me, and at this critical period, to come in presence of this learned Society to lay before you facts of very long standing, I may say of centuries duration, and which up to the present date remain open to the inspection and observation of all:

Having read a great deal lately in the newspapers, both English and Irish, as well as in the weekly medical periodicals, relative to the cause of typhoid and other fevers, the writers abstaining, in general, from the production of any real facts, seem to be unanimous in attributing such diseases, in their inception, to the decomposition of animal and vegetable matter. They trace the first rise of the malady to malignant effluvia emitted from manure heaps, stagnant pools, drains, sewers, cesspools, and to all such heterogeneous accumulations as are found near the dwellings of the poor and farming classes, as well as to the gases arising from the closets and closed sewers of the rich, who dwell in palaces and fare sumptuously every day.

After an experience of a quarter of a century as an Irish Dispensary Medical Officer, I venture to record my dissent from these conclusions. As a practical man, in charge of a large and populous district, together with a practice over 200 square miles, I need not say that I have had abundant opportunities of becoming familiar with the dwellings and habits of all classes of the community; and it is my firm conviction that the agencies above indicated cannot be actually productive of fever of any type. Were it otherwise, Ireland would ere this be depopulated from sea to sea, or at most but sparingly and thinly inhabited.

It is a well-known fact that, with rare exceptions, the farm yards of the Irish agricultural classes are simply the open spaces either in the front of their dwellings or close behind. The office houses, the cow houses, stables, &c., either ranging with the main dwellings, or actually forming a component part of them. The farm yard manure, carelessly heaped, in many instances up to the very doors, and in such a way that it often becomes a problem to the perplexed doctor, whose practice is desired within, how to effect an approach, especially when called upon in the dead of night, without sinking ankle deep in mire and filth, or perhaps coming to worse grief in the shape of a souse in the slough of despair.

Such is the state of affairs during the winter months—in the hot weather of the summer the pits from which the accumulated manure had been removed to the farm serve as a receptacle for slops and refuse of all sorts thrown from the houses. These slops, fermenting in warm weather, produce a green stagnant pool, the gases generated showing themselves in the form of bubbles on the surface, which in due time burst, and, of course, discharge their *supposed* noxious contents in the immediate neighbourhood of the dwelling with all its inmates, old and young.

In places such as I have very inadequately described, I may say I have rarely observed a case of fever of any type to occur. The average length of life is very high in many such places, and I may say also, that illness in many such places is almost unknown, save in the form of a common cold, or such diseases as are peculiar to infantile life and childhood.

In many instances, I am sorry to say, our peasantry live in a state of barbarism even worse than that already described—the farm stock being housed in the same dwelling as the human inmates, the manure thrown in heaps everywhere about the house up to the very threshold; the pigs and poultry fed upon the kitchen floor, and the refuse of the repast, together with the contributions from the guests—porcine and feathered—swept into a deep pit close by the fire-side (called the ash-hole or ash-pit), which is rarely cleaned out until it is filled to overflowing. Yet, even in such habitations as these I have found the families hale and sound—strangers to fevers and other diseases which, if the contrary received theory be correct, ought to be too familiar acquaintances.

Let me add an illustration :—Some eight or ten years ago, during the construction of the Newry and Armagh Railway, the small town of Markethill was crowded to excess with navvies and their families, there was not an available spot in the town, but was filled to suffocation—many rooms tenanted with two or more families at night. Notwithstanding all the filth and stench consequent upon the over-crowding, the season was one exceptionally free from disease generally, and in particular marked by the absence or rare occurrence of those of a febrile character.

Nor is my experience in these matters at all singular in what I have stated in reference to the continuance of vigorous health in the close neighbourhood of influences commonly believed to be of a noxious character. Clergymen of all persuasions meet with the same state of things in their walk of life, as well as Dispensary Medical officers, and the intelligent members of the Constabulary Force who, being brought by their statistical duties into close connection with the farming classes, are perhaps qualified to give an opinion as well as clergymen and doctors.

It is a fact that vegetable and animal life will flourish and thrive wonderfully in the vicinity of such places as I have already pointed out : grasses of all sorts grow luxuriantly around the borders of such places, and ducks and many sorts of waterfowls feed and fatten upon such stagnant pools, with their bills as deep into them as they find necessary to procure feeding from the bottom, oftentimes as far down as length of neck will permit.

Rats and frogs also live and thrive well about such places. I have recently seen a closed sewer, which runs through a farmer's yard, opened for the purpose of having it cleared out; it had not been opened for many years previously ; it was almost entirely filled with most offensive smelling matters. After the removal of the flags, which formed the covering, a number of frogs were found lodged together at one side of the drain, more than two yards from the opening into it, where they had collected to hybernate ; they were all alive, and had every appearance of health, and no doubt, were they permitted to remain a little longer time, they would have come forth from their retreat, of their own accord, in due season, to spawn.

I carefully examined the spot where the frogs collected themselves, and was unable to discover the remains of a dead one, thus showing that the gases generated in the sewer had no injurious influence upon them.

Familiar as I am with facts such as I have described, I own it has seemed to me passing strange to see it so confidently asserted that His Royal Highness the Prince of Wales must have caught the dire disease, which has so lately been the cause of so much anxiety to every loyal heart in the realm, from defective sewerage in the house of his noble entertainer.

"The wind bloweth where it listeth ;" and in my humble opinion it is the same with the seeds of disease.

Strange, indeed, are the laws of epidemics : at one time, small-pox rages, as at present ; at another, fever ; at another, scarlatina ; at another, erysipelas ; at another, *cholera;* whitlow, perhaps, and influenza, &c. Let it be *particularly noted* that the conditions productive of fatal disease are, in all cases, subject to little or no variation, and therefore, where the causes are perennial, as among the Irish peasantry, there ought to be no respite from the ravages of deadly maladies.

The facts, unfortunately for the theory, are perverse ; instead of a confirmation, they supply a refutation, to my mind, irresistable.

The conclusion to which all my experience tends may be expressed briefly, and will, no doubt, have been anticipated by my audience, viz., that the causes generally assigned as generating typhoid and other fevers are completely inadequate, and that it yet remains to be discovered from what mysterious sources those fatal maladies arise.

Dr. Rawdon Macnamara expressed, on behalf of the Society, the thanks due to Dr. Pratt for having come up from a distant part of the country to communicate his experience. At the time he (Dr. Macnamara) occupied the chair of the Society, he tried to impress on his hearers the importance of soliciting communications, such as that of Dr. Pratt, from their provincial brethren. They had a vast field open to them, and any communications which they might make to the Society would deserve consideration, and be received with respect and gratitude. The question of the communicability or transmissibility by sewer gases, with which Dr. Pratt's paper dealt, was one that required much consideration at the hands of that Society. He entertained strong opinions on the subject ; but he would not venture to trouble them with any lengthened observations, as he saw present among them sages of the Profession, men whose opinions ought to be received with all the weight that attached to pre-eminent sagacity, great experience, and unrivalled intellectual ability, and he hoped they would favour the Society with their views on the question. He himself held strong views as to the transmissibility through gaseous influence of various kinds of disease. He thought he could bring forward proofs of the transmissibility of scarlatina in various obscure ways. He believed that typhus fever, and pre-eminently typhoid fever could be transmitted through various forms of sewer poisons. Gas might be most offensive to the nostrils, and yet not capable of producing anything like zymotic disease. If they were to turn out the lights in that room they would have a most unpleasant odour. They knew what it was, or rather, thanks to the Corporation of Dublin, they did not know ; but presuming it represented carburetted hydrogen, he did not think that would be capable of conveying a poison that would produce disease. It might kill, but he doubted if it would communicate to the person who died of it that which would communicate the disease to another person. The most unfortunate thing about gas poisoning in other cases was, that the odours were not perceptible ; they were perfectly innocuous as to smell, and yet they carried death on their wings. He differed from Dr. Pratt on that point, although fully recognising the importance of his paper. The question was one well worthy of investigation, and it ought to be discussed separately from another important question, namely, whether the poison of typhoid was analogous to that of typhus. Whether they were analogous or dissimilar diseases, or sprang from the same source, was foreign to the question treated by Dr. Pratt. He had brought forward most powerful evidence that stink was not the cause of fever ; but the stink Dr. Pratt spoke of was different from that to which they attributed typhoid disease, although the most skilful chemist would find it difficult by the most careful analysis to discover wherein lay the distinctive difference between them. In the condition of affairs in the dwellings of the small farmers, described by Dr. Pratt, there was an important element wanting to the production of typhoid disease. He described deposits of decomposing matter and human ordure at the side of the hearth, but these were placed in a *cul-de-sac*, and along with them was deposited at the same time the very thing which they knew to be Nature's great corrector and deodoriser—turf ashes—so that if gas were formed there, it was absorbed at once, instead of being disseminated through the house. This was different from what prevailed in the ordinary water-closet. He believed that a great deal of the morbific poison which was generated by water-closets arose from the communication with tidal rivers. When the tide was out, the tube which passed from the closet was filled up with gas, and when the tide rose it sent back the gas, which found its way out through the seats and pans of the water-closets. It was a great error to suppose that, if the pan of the water-closet contained water, it would intercept the gas. The moment the water in the pan was fully saturated with gas, the gas, if it continued to be forced up, bubbled through the water, and that form of typhoid poisoning was carried into the house. He appealed to Dr. Stokes, one of the greatest authorities on fever in this or any other country, whether he was not justified in saying that in former days they did not find the symptoms, which were now described as typhoid fever. He was certain that at the commencement of his professional career there was an absence of these particular symptoms. On looking at the writings of Sydenham and others, they could trace various other forms of fever, but he could not find in these works any of the symptoms of that form of fever now known as typhoid. He believed that that disease was unknown in the old times when the offices were generally situated at the bottom of the gardens, and when there was no risk of contaminating the air in the houses by sewer gases. He believed that that accounted for the absence of typhoid fever in former days ; whereas modern civilisation, with its many advantages, was accompanied by some evils, one of them being the returning of gas into their houses by means of water-closets.

Dr. Darby said he could corroborate every word of Dr. Pratt's paper by his own observation. It was most valuable, because of the theories that were now put forward, not only as to contagion or infection spreading from the diseased to the healthy body, but also with regard to its production from manure heaps and decomposing organic matter. There was only one cause which he thought would account for the spread of disease from human being to human being, and that was overcrowding. All his life he had seen the healthiest human beings reared in farm-yards, the children playing from morning till night on the dunghill, and the pigs and fowls running about the house. The more filth about a farm the richer a farmer would be. His object was to make manure, and he did it, but without detriment to the health of the inhabitants of the farm. A few months ago he was attending a case of small-pox in the dirtiest house he knew. It was filled with children; it was filled also with cocks and hens, and he was not at all sure that the pig did not sleep under the bed. He had the curiosity to measure the room in which six children were sleeping. It was seven feet wide by nine feet long, and six and a half feet high, and had but one small window. Six children were sleeping in one large bed in that room, and one of the children had small-pox. He recommended the removal of the child to hospital, but the parents would not consent. He then told them to remove the other children from the room, but this could not be done, as there was no other place to put them. This was three months ago, and not another case of small-pox occurred in the house. The overcrowding of people in small lodging houses, did, he believed, generate fever, but he denied that manure heaps or gas emanating from decomposing matter would do so. Practically, he thought the wisest course was to leave a vent for the gas to escape and to prevent its accumulation, and in some places that was done; but in truth, he did not think the disease called typhoid fever could be traced to any distinct source. In these farm-yards and houses the people went on from year to year with the same dirt, and there was no small-pox, typhus, typhoid, or scarlet fever among them. A change took place, an epidemic set in, and then disease spread among people who had been free from it for years. Some gentlemen said these diseases could be stamped out. He doubted the possibility of this being done. They did not stamp out the cattle disease, or the grape disease, or the potatoe disease. They were fighting with an unknown enemy, and they were not prepared with the proper weapons to fight him. He did not mean to disparage cleanliness—quite the contrary. He believed it possible to stamp out endemic disease by improving the habits and increasing the comforts of the people. They might stamp out scrofula and cachexia by sanitary and other measures, but he did not think they could stamp out epidemic disease.

Professor Cameron thought that Dr. Pratt in his opening had stated that which was not generally received in science. He stated that those who wrote on typhoid fever said it was produced from the emanations from decomposing animal and vegetable substances. Those who had studied the etiology of the subject found no such statement made by any competent authority. It was stated that animal matter undergoing decomposition, and air contaminated with fæcal emanations would lower the vital system and predispose to disease, but he did not think it was stated that the disease could be got from sewer emanations alone. There must be the virus of the disease present in the decomposing matter before the emanations from it were capable of giving the disease, but decomposing animal and vegetable matter *per se* was not likely to produce it. That decomposing animal matter such as excrement, was a great cause of the disease was highly probable when they considered the enormous amount of fæcal matter from typhoid patients which was disseminated over the country. It amounted, he calculated, to one million four hundred thousand pounds weight deposited every year. Suppose the number of cases in the United Kingdom every year was 200,000; sometimes in England alone they amounted to 150,000, and 50,000 for Scotland and Ireland was not an extravagant figure; and suppose there was diarrhœa in each case for a fortnight, at the rate of a few ounces per diem, they would see what an enormous quantity of excrement containing a certain amount of typhoid poison was disseminated over the soil of the country, a portion of which found its way into the water wells. Typhoid fever was as prevalent in the country as it was in the towns, as the recent statistics of Dr. Clarke showed. That gentleman, in a Paper read before the Medical Society of Edinburgh, laboured to prove that it was impossible to destroy the virus of typhoid fever, because the sanitary legislation could not reach the rural districts, and he found there were as many cases of death from typhoid fever in the rural districts as in the crowded and unwholesome lanes of the city. He thought that the poison of the disease was as likely to be produced in the rural districts wherever there were persons suffering from the disease. They could readily understand that in towns where excrement was thrown into the yards or passed into the soil-pipes, emanations from fæcal matter would carry with it solid particles. Suppose the virus of the typhoid was a solid, they could understand how strong currents of air passing into houses from pipes would carry with it the virus of the disease. He had inspected some large public institutions where typhoid fever was prevalent, and in a great number of cases he had no doubt the disease was produced by an opening into the soil-pipe. Dr. Ferguson, of Edinburgh, had directed attention to the fact, that even the newest leaden soil-pipes were liable to have fissures formed in them, by which the gas from decomposing animal matter escaped into the houses. He had seen fissures in new lead pipes in houses supplied with water from Loch Katrine, and other sources equally pure, and he found that the typhoid poison could have been introduced only by these fissures. Some time ago Mr. Richardson asked him to examine some water that he expected had produced typhoid fever in seven members of one family. He believed that in that case the first person affected communicated the disease to the other members of the family. The water contained from 16 to 18 grains of solid matter to the gallon, and he gave his opinion that there was a considerable amount of sewage contamination. It was found that the soil-pipe discharged itself into a *cul-de-sac*, and that there was no way for it to get away except into the well which supplied the house with water. A specimen of the water used in the County Longford Institution was sent up to him for analysis; it was found to be contaminated with sewage, and subsequent inquiry showed that there was a rat hole in the sewer, which was only three feet apart from the shaft of the well. A similar case occurred in the Convent of Clondalkin. The water was found to be bad, a rat hole was discovered by which it communicated with the sewage. He knew the case of a well in the County of Wicklow, at a place which he was in the constant habit of visiting during the summer. The water was abominable and disgusting, having the odour of sulphuretted hydrogen, but no case of typhoid fever had occurred there for fourteen years, though the family were in the habit of drinking this water. It was from a well in a stable yard. If excrementitious matter *per se*, could produce typhoid symptoms, there never was a case where it should have been more thoroughly developed than in this instance, where the water contained from 20 to 30 grains of solid matter; whereas he had found in cases where persons had taken up the virus of the disease from water, the organic matter it contained did not exceed three grains per gallon. As to the spreading of the poison, that was altogether dependent on its volatility. Some experiments recorded in the *Journal des Hopitaux*, showed that the poison of small-pox was volatile at 40° centigrade. The poison of the contagious pleuro-pneumonia of cattle was volatile at a temperature of 45 degrees, He thought it was the same with all these different forms of epizootic diseases. The different kinds of poison had different degrees of volatility. Syphilis and vaccinia could only be propagated by actual contact; but when they come to such diseases as typhus and typhoid, they were altogether in the dark.

Dr. Stokes was glad to be present at the reading of Dr. Pratt's Paper. He was the first to bring forward the important fact connected with the prevalence of fever in Ireland, that while the presumed causes of fever are permanent, the effects are not permanent but intermitting, or at least remitting. The dung heaps, the imperfect sewage, the filth of the country farmers' places formed a permanent institution. The occurrence of fever was epidemic and inconstant. That was one great fact not easy to get over in the theory of the septic origin of fevers. He remembered a good many years ago when there was a tremendous epidemic of fever in certain parts of Ireland, and especially the southern portions; and when Limerick, Cork, and other towns were the centres of the most terrible plague, the town of Killarney might be said to have escaped. The Grand Jury of Kerry, greatly struck with this, directed his brother, who was County Surveyor, to make a survey of Killarney, which he did, and the result was something startling. It was proved that there was, by some enormous proportions, a greater quantity of putrescent matter in Killarney than either in Cork or Limerick. The number of cubic feet of putrescent matter to each individual was something incredible. A good deal had been said of the distinction between typhus and typhoid fevers. He should be sorry that that Society adopted those hard and fast lines of distinction between different forms of essential disease. They were all very well on paper and in the books of nosologists; but the practical man who met with these diseases in great numbers, would tell them that there were many cases which he could not put clearly into this category or that category. Many of the authors who contended for these hard and fast lines of distinction, had not observed or practised in this country. Their experiences had been drawn from the London or Edinburgh Hospitals, and they had not practised much, or at all, in Ireland. If they did they would have an opportunity which did not occur in English Hospitals, of seeing an entire family in the wards of an hospital at the same time, both the parents and five or six of the children; and in that group of cases, where one cause most probably produced the disease, they would meet with every possible variety of fever, well marked petechial typhus, non-petechial fever, pythogenic fever (to use the newest phrase), or enteric fever, simple fever, rheumatic fever. Therefore it seemed a very difficult matter to say that these diseases are essentially distinct. He had lately read a paper on the "Correlation of Zymotic Diseases." He would go a step further and say, it might yet be a question whether the various cases of zymotic disease were not only correlative but convertible. With respect to the question of stink, the tendency of modern sanitarians was too much confined to the removal of nuisances. They thought they would do all that was required by preventive medicine. Preventive medicine was a development of knowledge of our own generation, and promised to be one of the most glorious products of the present time—far beyond curative medicine, for that depended on the slow advance of medical science, which all depended on the characters and the training of the professors of curative medicine. But preventive medicine implied the cure of the masses of mankind and of the population at large. It depended on wise legislation. He believed the sources of epidemic diseases were not yet known. Dr. Pratt gave utterance to the same idea when he said, "the wind bloweth where it listeth." The great Humboldt, in his Cosmos said, that among the various questions that involve human inquiry, there was none more obscure than the origin of epidemics. It was a fashionable doctrine that endemic and epidemic diseases could be removed or destroyed by what was called sanitary reform. The argument on which the doctrine was based was this: an epidemic disease appears; sanitary measures are adopted, and the disease disappears; but this argument was really a weak one, when they reflected that epidemic diseases were like diseases in individuals; they had this appearance, their growth and their spontaneous subsidence, and the question was whether this subsidence was the result of sanitary measures or merely the result of a general law. The greatest disgrace had come on the profession of medicine, by gentlemen putting forward remedies for this disease and that disease, that would disappear without any remedy at at all, and attributing the recovery of their patient to the last remedy applied. And so it was with epidemics. They could not then necessarily attribute their cessation to the adoption of this or that curative remedy or preventive measure, or sanitary reform. There was another matter which Professor Macnamara had not alluded to, but which he knew was in his mind, for he had frequently spoken to him about it—the great error of attributing great phenomena to a few limited number of causes or to one cause. They only knew of one cause capable of producing great phenomena, and that was the cause of all the phenomena of the world and of man—he meant God. They did not know of any great phenomena or series of phenomena that was not the offspring of an infinite number of causes; and to say that typhus results from emanations proceeding from the overcrowding of human beings, or that pythogenic fever proceeds from the putrescence of matter in which the seeds of typhoid fever had been mixed, would seem altogether wrong. Dr. Graves, when there was an outbreak of Cholera in London, wrote his celebrated article against the view of the *Times*, in which he showed the folly of attributing it to the sewage. He thought it was settled that bad odours were not in themselves necessarily deleterious. It was quite possible that one odour might be deleterious and another not. Labourers working in knacker's yards and in sewers did not appear to be more liable to disease than other persons in the same class of life. Dr. Pratt, coming from the North of Ireland, was well aware of the frightful odour from the maceration of flax that pervaded the country at certain seasons, yet it had never appeared that it had been the cause of an outbreak of typhoid or any other fever. With regard to sanitary reform, civilization required that all these deleterious influences should be removed—not merely bad smells, but everything, whether of a moral or physical nature that could retard the healthy development of the human frame. They should inquire whether sanitary reform acted simply by extinguishing the germs of disease, or whether it acted by the improvement of the general health of the population, thereby enabling the human body to resist contagion, or, if it yielded, to bear up well against the disease. He believed that this was the true way of looking at sanitary reform.

Dr. Henry Kennedy said it must be remembered that epidemic influences did not affect human beings alone, and whatever explanation might be given they must take the fact that epidemics had existed everywhere from the earliest periods of recorded time. They had evidences of them in the air, in the sea, and under the earth. Dr. Darby had alluded to the epidemics in cattle and vegetables, as well as in men; and they were mentioned in the Bible, in Homer, and other ancient writings. So that any attempt to explain epidemic diseases coming on us because we happened to live in a particular condition as to cleanliness or otherwise was not satisfactory. There were plenty of instances on record where severe epidemics occurred in the midst as it were of cleanliness. Coventry was a model town for cleanliness, and yet there was not a town in England where the small-pox had been so bad. As to the case mentioned by Dr. Cameron of bad water being used by a particular family without ill effects, he (Dr. Kennedy) would venture to suggest that probably the sulphur in the water might have been antagonistic to the effect of the poison. He could not go with Dr. Cameron in saying that sewage matter was not capable without something else of causing typhoid fever; for there was evidence to show that mere sewer gas without anything else would account for it.

Dr. Charles Frederick Moore observed it did not appear that the conditions of country dwellings, as described by Dr. Pratt, resembled town or city tenements, the former having mostly large and wide chimneys which insured ventilation, and all offensive matters were preserved for the farm. In cities and towns, too often, the tenements were contaminated by the soakage of the walls, basement, &c., with sewage. Besides, he could not, from five years' experience of a hospital in the county Armagh, agree with Dr. Pratt that typhoid fever was unknown there, having treated very many severe cases whilst there. He also had some cases of that fatal form of fever known some years since as the Armagh fever, under his care in the North. He regarded typhoid excrementitious matter as peculiarly dangerous. However, he felt indebted to Dr. Pratt for his communication, coming up as he had miles from the North to deliver it before the society.

Mr. Richardson observed that it might be of some interest in connexion with the question so kindly brought before the society by Dr. Pratt, to give a few of the leading particulars of the cases that occurred in the house at Kingstown just alluded to by Professor Cameron. He (Mr. Richardson) was requested, on the 22nd January, 1871, by his friend, Dr. Newland, of Kingstown, to see with him some cases in a house there, and to visit which Dr. Newland himself had been asked only the day previously. Dr. Newland found that three of the children—girls—had been nine or ten days in typhoid fever, and were, at his visit, in a hopeless condition. Two more—young men—had been ill only for a couple of days, and another (a young woman) had taken to bed the day he first saw her. On my arrival I found that one of those first attacked had just died, and that, as Dr. Newland anticipated, the other two had but a short time to live. These three cases had abdominal symptoms, and the peculiar rash of typhoid fever, and one of them had besides well marked *coma-vigil*. Of these two, one died on the 24th and the other on the 26th January. The three, when Dr. Newland first saw them were, in fact, in the typhoid condition. Of the three others attacked (the two young men and the young lady who was about twenty-three years old) the young men had the fever mildly, but the latter lapsed into the typhoid state, and had a narrow escape of her life, the chest and abdominal complications having been very severe. These three also, had characteristic typhoid spots. The seventh, and last attacked, a fine young man, continued well for several days subsequent to the seizure of the last-mentioned cases, and was sent to a relative's house in Dublin to remove him from the local influence that favoured the development of the fever in his brothers and sisters. However, he was not long in Dublin until he was attacked with vomiting, got alarmed, and returned home. The parents in their anxiety for his safety sent him back to Dublin and to the *Pension-Medicale* in Charlemont street, whence he was transferred to one of the pay wards of the Adelaide Hospital, and was placed under the excellent care of my colleague, Dr. Little. Here, unfortunately, during the progress of the enteric fever he was attacked with scarlatina and died. He likewise had the characteristic typhoid eruption, and during the decline of the scarlatine rash new typhoid spots made their appearance. Although he (Mr. Richardson) had no evidence to adduce as to whether this almost simultaneous outbreak in one family was spontaneous or dependent upon the presence of typhoid germs in their drinking water, of which the young members partook freely, nevertheless he thought there could be little doubt from the large amount of nitrates, nitrites, ammonia and common salt, Dr. Cameron's analysis proved it to contain, that there was an intimate connection between the outbreak and the contaminated water. To add to the misfortune of the father and mother of this family, another of their children died of phthisis on the same day on which the death of the first case happened from the enteric fever.

The Rev. Professor Haughton, F.T.C.D., said that about three years ago there was a slight but significant outoutbreak of typhoid fever among the students of Trinity College. Six students took ill; one of them died, and another very nearly died. The opinion among their brother students was very early expressed as to the cause of the disease. These six gentlemen were all teetotallers; they never drank beer at Commons, they drank water only. An investigation was made into the well water, which was at the back of the college kitchen, and was used for culinary purposes. It was a very well tasted water, but there had been some unusually high tides shortly before, and the Provost suggested, what was not an improbable explanation, that the high tides kept back the sewage, and that some of it flowed back and got into the well. On examination by Dr. Apjohn the water was found to be very bad, and they had no hesitation in attributing to it the outbreak of the fever. As to the general question of the origin of epidemics he (Dr. Haughton) disbelieved in the atmospheric theory. Some years ago they had a discussion on the outbreak of cholera, and it was demonstrated by careful investigation that the disease was brought in by some one individual who communicated it to the next, and so it went on and extended; and that there was no such thing as a spontaneous outbreak of that disease arising from any condition whatever of filth or of cleanliness. Miss Nightingale said she had seen herself small-pox arising in the corner of a dirty ward, but he thought it would require stronger evidence than that of Miss Nightingale, excellent authority as she was, to satisfy them on that point. Their scientific efforts ought to be directed to search out and explain at an early stage of epidemics the causes that gave rise to them. The cause would be generally found to be contagion, or passing from one to another, or drinking water or other corruptions. When cholera appeared in Moscow, in 1831, an accurate account of its progress was taken by Blumenthal, and for the first three or four hundred cases he could tell in each case who it was the individual got it from; but when the cholera became more diffused the clue was lost. If they ascertained at an early stage of an epidemic that the disease was communicated in a particular way the inference, when it became more diffused, was that it had been similarly propagated, although they might be unable to trace its history in its later stages. As to the influence of dirt in causing disease, he thought it was exaggerated. Good food, and an occasional glass of spirits, was a far better preventive of disease than cleanliness. What made epidemics fall so heavily on our poor people was not the bad air they were dwelling in, but the miserable food they eat and the exposure to which they were subjected.

Dr. Mapother reminded Professor Macnamara that the defect in the water-closets of which he complained could be effectually remedied by adding a ventilation pipe to the soil-pipe, so as to prevent any of the noxious gases that might be generated from coming into the house. He believed that every one of these zymotic diseases required a seed just as much as an oak did; and he was not aware of any work where the statement was made that emanations from excrementitial matter would produce typhoid fever, unless it contained the specific poison-germ. He heard Sir Dominic Corrigan say that when he and Dr. Lyon Playfair were making a tour through the County of Kerry, a farmer, who delighted in the amount of manure outside his house, told them that he believed in the preventive virtue of the smell, and said the fever was killed by the stink. He feared this had produced some influence on Sir Dominic. He had often heard him say that these diseases were not to be stamped out. They had all heard with pleasure the eloquent observations of Dr. Stokes with regard to the great advantages of sanitary reform. Anything that would tend to improve the habits of the people would be of great benefit to the country. Unfortunately many of our countrymen carried with them to America their shocking habits of collecting all the filth they can round their dwellings, and keeping their bodies in a state of dirtiness, and if a change could be effected not only in the state of our towns, but in the habits of the people, they would do more credit to their native country when they emigrated to the New World.

Dr. Richardson suggested that the Vice-President had lately met some cases bearing on the subject before the Society.

Dr. Kirkpatrick then said—"About the middle of last Summer I treated, in conjunction with my friend, Dr. Gordon, nine cases of typhoid fever in one family, residing on the Donnybrook road. On the occasion of the first, which was a mild but well-marked case, I cautioned the rest of the family against the use of the pump, which was in suspicious proximity to the soil-pipe. Nevertheless they continued to drink the pump-water, preferring it to the pipe-water from the canal. During the next fortnight eight other cases occurred in the family, all presenting the rose spots, and the other well-marked symptoms of enteric fever. About the same time eighteen cases of this disease occurred in a training school in North Great George street. Most of these cases were treated by Dr. William Moore at Sir Patrick Dun's Hospital, and at his suggestion the drinking water of the school was examined, and was found to be extensively contaminated, and a communication discovered between the drain and the well." My friend, Dr. Darby, will scarcely argue that these cases were produced by epidemic influences. In the course of my private practice, I met with several cases of this disease every year, but in my large public experience as one of the Medical Officers of the North Dublin Union, I have never met a single case, although there are in that institution a large number of inmates of all ages. My colleague, Dr. Rutherford Kirkpatrick, is present, and can add his testimony as to the total absence of this form of fever, which I am led to account for by the fact that there are no water-closets, that the lower wards and passages are flagged, and that there is no opening whatever within the building which communicates with the sewers of the city. I quite agree with the views so ably brought before the Society by Dr. Cameron, and I am fully persuaded that as long as the present system of water-closets, cesspools, and deep drains is maintained, so long will typhoid fever prevail, not as an epidemic only, but as an institution amongst us.

Dr. Stokes said lest it might be thought that he was decrying sanitary reform, he should state that it was not his meaning or intention. It was a good many years since sanitary measures, extensively adopted over India, were put into practice in the City of Calcutta. A magnificent system of drainage, and a magnificent water supply, probably the most magnificent of any modern city, were established there. The result was that while the cholera had continued in that portion of the town inhabited by the natives, in that portion of the town which was purely European the cholera had simply disappeared. So that Calcutta, formerly the most unhealthy town in India for Europeans, was now the healthiest. That was one important fact in favour of good drainage and pure water.

Dr. F. T. Porter could not agree with the statement that no fever could be caused by emanation from decomposing animal matter. Some years ago a severe epidemic of fever broke out in one of the islands of Arran, on which occasion he himself contracted the disease, and it was traced to the gas coming off from decomposing fish *débris*.

Dr. Pratt replied briefly. He expressed his gratitude for the manner in which the Society had received his paper. Dr. Stokes, he said, had anticipated him in another which he had promised to prepare on the different types of fever, for he believed they were all identical. He repeated his opinion, that stink was no cause for fever of any kind, and if it were there would be no one at all now alive in Ireland.

WEDNESDAY, MARCH 6, 1872.

SYPHILIS CORPUSCLES.

THE intense interest excited by the alleged discovery of Dr. Lostorfer rapidly reached beyond Vienna, where it was first mentioned. Our own columns have testified to this, and only last week we reproduced a letter written with much enthusiasm for one of our American contemporaries. We have also given translations from other journals, but still the subject is forcing further attention.

As it is unnecessary in a brief summary to go over the old ground, and as we have already given much from the Vienna papers, we will here print a translation from the other German capital forwarded to us by Dr. Arthur E. Barker. It is from the *Berliner Klinische Wochenschrift* of 27th January, No. 5, and has been sent to us from Bonn by Dr. Arthur E. Barker :—

In the meeting of the 12th of January, 1872, of the "Gesselschaft der Aerzte," in Vienna, Dr. Löstorfer spoke about the diagnosis of syphilis through microscopic investigation of the blood. According to the views of the lecturer, the examinations which have been hitherto undertaken, have been unsatisfactory, because they have been been made with magnifying powers too weak for the purpose, and fresh blood alone has been used. Dr. Löstorfer has avoided these errors. He began in August of the previous year with material from the clinic of Prof. Zeissl. The blood was taken from syphilitic individuals, and after a space of three or four days he always found small glancing bodies, on which he could at times discover processes. It was then seen that these bodies increased by bud-formation. New individuals were formed, which again showed a secondary proliferation by budding. On the addition of various fluids these little bodies shrunk up, especially with sugar water, and Pasteur's fluid mixture. These were surrounded by vacuole, and enclosed.

These results were so constant that Dr. Löstorfer could diagnose with certainty the presence of syphilis, by the propagation of these bodies. He had subjected himself to eight or ten trials which were given him partly by Prof. Stricker, partly from Prof. Hebra, and every time he had recognised among the range of preparations, the syphilitic blood correctly. The number of syphilis corpuscles to be found in the field of the microscope was frequently fifty, sometimes less. The period of their development was the third or fifth day; in many cases they appeared in twenty-four hours.

Too low a temperature retards the development, yet it can go forward unhindered at about from 8 to 10 degrees C; together with the decrease of syphilitic symptoms through therapeutic treatment, these little bodies disappeared also.

Further investigations must teach us whether these corpuscles first take their rise with the syphilis, or whether they are already present in healthy blood, and are only favoured in their development by the affection.

After the lecture, which excited great interest, Prof. Skoda congratulated the lecturer on his discovery, as likely to form a new era in this study. Prof. Stricker, as well as Prof. Hébra, confirmed most completely the accounts given by him.

We have already stated that Drs. Wedl, B. Kraus, and other leading men in Vienna have hastened to dispute the discovery, and one of the journals has spoken of the solemn burial of the corpuscles.

We cannot but feel the greatest hesitation at accepting the discovery, and while we signalise the discussions at Vienna as important, and dwell upon the interest they have excited, we acknowledge it is no part of our duty in these columns to do more. At the same time we are desirous of giving such information as our readers will naturally expect. We therefore ask their especial attention to the following letter, written to us by an esteemed *confrere* resident in Vienna :—

VIENNA, *February*, 1872.

The winter Semester is drawing to a close, and a large number of the students who have been in attendance upon lectures during the winter, are leaving for their homes, or for the warmer and more congenial climate of Italy.

The private classes were unusually well attended during the present session; there are several to join for which it is customary to give in one's name from six weeks to two months previously.

The American students number from forty to fifty, the majority of whom are following up one or more specialities. Dr. Bumstead, of New York, well known to the Profession as the author of a work on "The Pathology and Treatment of Venereal Diseases," attends daily Hebra's lectures on "Diseases of the Skin," Sigmund on "Syphilis," and several others.

Jaeger has several private classes daily, numbering each from eight to thirteen students. Schrötter on "Diseases of the Throat," Politzer and Grüber on "The Ear" are all equally popular in their specialities, the usual fee is twenty florins for foreigners, and ten for residents or natives.

At the last regular meeting of the Medical Society of Vienna, the subject of the syphilitic blood corpuscle was brought forward for discussion; much was said during the course of the evening both *pro* and *con*.

Dr. Löstorfer, the discoverer of this supposed peculiarity in the blood of syphilitic patients, claims that he can with the microscope decide whether or not the blood of the individual submitted to him for examination is syphilitic, by the mere presence of this new feature; this he has succeeded in accomplishing in a large number of specimens of blood submitted to him for test.

The corpuscle, as described by Löstorfer, is on an average about one-sixth the size of a normal human blood disc, spherical in shape, of a greyish appearance when examined under a strong reflected light, but not visible until forty-eight hours after the blood has been taken from the body.

Hebra is inclined to favour the new theory, but, as yet, is cautious about committing himself to it.

The opponents of the theory declare that precisely the same appearing corpuscle is found in normal and in variolous blood, and that it is nothing more nor less than disintegrated or decomposed white corpuscles; the fact of its not being visible for forty-eight hours after the withdrawal of the blood from the body, gives, in our opinion, support to this view of the theory; again, it is suggested that the supposed corpuscles are fat globules which are deposited by the finger when it is pressed upon the glass upon which the blood for examination is placed under the field of the microscope.

The subject is being patiently and earnestly investigated by many clever men here, and it is to be hoped that a decided result will shortly be arrived at.

The President of the Society has appointed a mixed committee, consisting of Rokitansky (the elder), an eminent microscopist, a botanist and syphilographer to investigate further the subject, and report their views to the Society at an early day.

◆

THE CONJOINT EXAMINATION SCHEME FOR IRELAND.

We learn that the College of Physicians of Ireland have rejected the scheme laid before them by the Conference of Delegates from the various licensing bodies. The Board of Trinity College have accepted it with the exception of that clause which entitles any person who has passed the Conjoint Examination to demand their degrees. It appears that the Board wish to retain the power of imposing some further test on candidates seeking the University M.B.

All the Irish Licensing Bodies have now given expression to their decision on the scheme proposed to them for Conjoint Examination with the following result:—

The University of Dublin has accepted it, subject to an important modification.

The Queen's University has rejected it absolutely.

The College of Surgeons have practically rejected it.

The College of Physicians has rejected it.

The Apothecaries' Company has accepted it unconditionally.

It must be quite obvious that no compromise is possible which will include all the Licensing Bodies in Ireland, and if a settlement can be arrived at at all, it must exclude some of the "medical authorities."

Nothing, however, has occurred to render improbable the formation of a Conjoint Board between the College of Physicians, and we are glad to think that this instalment of the hoped for coalition may yet be acheived. We should earnestly hope that mutual concessions might be made for the purpose of bringing the University of Dublin and the Apothecaries' Company into the scheme.

Should such a coalition be considered practicable, the Queen's University will stand aloof and trust to its own educational and licensing resources for sustenance. Its interests are so diverse from those of the other bodies that it was hardly to be expected that they could coalesce to form a compatible mixture.

In the first place, the Queen's University gives its M.D. to Students in Arts, and does not restrict them to graduates as the University of Dublin does. It would not be reasonable to expect that the Licensing Corporations would concede the same special advantages to the Queen's University which, for the purpose of fostering high-class education, they accord to Trinity College. Moreover, the Queen's University gives its M.D. for £5, a price so far removed from what has always been considered a legitimate and reasonable charge that it could not be expected that an intermediate fee could be agreed to. If the Queen's University were to raise its fee to meet the Licensing Corporations, it would at once lose the principal attraction which its degrees have for students. If the Corporations were to come down to any such sum, they would speedily die of inanition.

These considerations go to show that the Queen's University has been the disturbing element of the Conference, and they inspire the hope that a Conjoint Examination Board, which shall give an honest high-class professional qualification in all subjects, may yet be practicable in Ireland.

◆

THE QUACK FRATERNITY.

On Friday last at the Central Criminal Court, Mr. Poland, the Treasury solicitor, appeared as a public prosecutor against a man of the name of John Alexander Barnes, who was represented as the possessor of an American diploma of doctor of medicine. The prisoner, who by the advice of his solicitor pleaded guilty, was charged with publishing and causing to be sold certain obscene and filthy books. He had lately resided in Lonsdale square, Barnsbury, having for some time previously acted as factotum to the notorious quack, Dr. Smith, the great M.D. of Jena, with various aliases, member of the Metropolitan Medical College of New York, and of the Reformed Medical Society of the United States of America, whatever this may mean; for if such a society ever existed, which we much doubt, we would most humbly draw the attention of this most august body to one of its members on this side of the channel who needs a very considerable quantity of the mixture of "Reformed Medical Society" to make him an honest, respectable man. And now we have one of his precious progenies, presumably setting up business "on his own account," but actually in league with him, as the evidence states that Dr. Smith's advertisements always appeared along with the prisoner's in the newspapers. The object of the prisoner was evidently, by means of the advertisements to call public attention to a book entitled "The Secret Friend."

Some time since, when evidence was given in court that a corporal of the Guards had committed suicide after receiving some letters from Burton crescent, and reading a few chapters of a book from this same scoundrel Smith, the title of the publication was "The Warning Voice." Now we have "The Secret Friend," and if there is one member of this filthy gang we should enjoy to see soundly flogged more than another, it is this *soi-disant* Secret Friend. And now let us briefly analyse the evidence against Barnes.

Mr. Poland said that at Bow street the prisoner was represented by a solicitor, who, on seeing the filthy nature of the work, at once said it ought to be destroyed, and the prisoner gave his consent to the destruction of the book and all papers of a similar character. While at the court, however, the prisoner was observed to make some remark to a person near him, and that person at once left and went in a cab to the prisoner's house. A police officer followed in company with the prisoner, who, on the way, said he had only a few copies left. On arriving at the house two men were bringing out bundles of these books. It then appeared that it was the object of the prisoner to have the bulk of the copies removed, so that only a small quantity should be destroyed. Six or seven hundred copies were found and destroyed. The police also found some copies of another indecent book, but the prisoner objected to their removal; and, as the police were not armed with a search warrant, they were unable to seize them. Some correspondence then ensued between the Solicitor to the Treasury and the prisoner's solicitor, in the course of which the latter expressed the readiness of the prisoner to give up or destroy everything he possessed of an indecent character, and his ignorance of having infringed the law. Subsequently, at the instance of the Treasury, the prisoner gave up to the police nearly 2,000 copies and 112 stereotype plates of the various works, and he admitted he had published about 3,000 copies at a time.

The prisoner's solicitor, Mr. Ribton, asked the Court not to inflict any punishment upon him. He had an American degree, and had resided a considerable time in the United States. He had been under the impression that in circulating this book he was committing no criminal offence. Every publication of an indecent nature had been given up, and if there had been any attempt to prevent the police from getting everything of this kind it was without his knowledge. The prisoner was determined *not to* repeat the offence.

And now what is the result? The excuse is allowed that "the prisoner might possibly be ignorant of the English law on the subject," and he is permitted to leave the court upon his own recognizances. Ignorant of the law when he had for some time previously been employed in the same nefarious practice by Smith and Company!

Ignorant! that it was against the usages of civilived society to disseminate the vilest blasphemy and indecency that man could concoct? Ignorant! that it was wrong to make one of the most useful institutions of the country—the Post Office—the medium to thrust this immorality and corruption into respectable homes? We pause for a reply, as we cannot understand why "the Government did not wish to press for punishment." What security has society that this man will not shortly turn up under a new guise, as the whole gang of them have done at various times? And why, we would ask, is not every newspaper suppressed which admits the announcements of these miscreants? This would be, no doubt, a sweeping measure; but the wholesomeness of the lesson would be seen in many ways, and it is one that must be learned sooner or later.

◆

Notes on Current Topics.

Thanksgiving Day, 1872.

Yes, we have seen the great procession that has made the 27th February a Red Letter Day to thousands of loyal citizens. God has been ostentatiously thanked with all the pomps and vanities of this world that a great country could bring together. The satisfaction at the restoration of the Prince evinced by the shouting, frantic thousands, has found an echo in the hearts of millions of others, and should bring Sovereign and People into closer alliance than ever. Church and State have been present, and vied with each other in the effort to prove the greatness of the occasion. All sorts and conditions of men have congratulated the Queen as never monarch before was felicitated. But in the midst of it all one thing in our minds has been sadly wanting. Military pomp was of course represented, but what was that but the mere trappings of the state? When the heir to the crown lay at Death's door, what had soldiers to say or to do? No! Doctors were then the need of the Prince as they are of private individuals. The Queen, the Princess, the Nation, all turned to medicine for aid; and when the danger was over, and the crisis was past, the gratitude was felt to be due to our art. Where then should medicine have been on the Thanksgiving Day? Should not the art of healing have taken precedence of the art of war, *i.e.*, killing? We think that as Her Majesty rode in State by the College of Physicians the thought might well have been present that much was due to medicine. The day of thanksgiving was an occasion on which to confer full and adequate honours on a considerable number of medical men. True, a K.C.B. has been conferred on Jenner, who should have been made a Peer, or at least a Privy Councillor. Dr. Gull has got a baronetcy and a court appointment, and this is what he might have expected. Dr. Lowe, who watched patiently and did his best, seems left out in the cold—why? Others, too, we might mention, whose names are familiar as court doctors, but who were not sent for or would have been glad to do their best. Had all these been honoured we might have been encouraged, but no! medicine is as much neglected as ever in England, while in all other countries the Profession is honoured by marks of Royal favour, and indication of social position, from which, here, it seems, we are always to be excluded. While no one rejoices more heartily than we do at the recovery of the Prince and the success of the great demonstration, we hold, that such an occasion ought to have been seized to redress an injustice keenly felt by all members of the Profession. We will even go farther, and add that the few tickets to St. Pauls, given to members of the Profession, compared with the numbers for other callings is a disgrace to the Lord Chamberlain who should have perceived that on that occasion at least, medicine ought to have been prominent.

The Prince of Wales.

It is satisfactory to learn from a reliable source that the Prince's convalescence has not been retarded by the fatigue and exposure of Thanksgiving Day. It seems decided that the Prince and Princess will pass a few weeks in the South of Europe. It is a pity that repose could not be found in some snug resort of our own island. Those who believe the Prince's illness arose from any defect of drainage, will not fail to remember that there is not a town in Southern Europe where the sanitary arrangements are not detestable. It shows how little his advisers can believe in the theories of our contemporaries, when the Prince is advised to sojourn in districts where a properly trapped drain is rarer than a black swan, and where the majority of so-called water-closets constantly exhale smells, compared with which an open drain is sweet perfume.

New Method of Giving Chloroform.

A contributor of the *Australian Medical Gazette* communicates a new method of administering chloroform, which he maintains is rapid, convenient, and safe. He acquired his first knowledge of the value and efficacy of the method in the case of a medical man, to whom he had been called upon to administer chloroform for opening an abscess. The patient, however, refused to receive it from any one's hands but his own, and proceeded to put himself under its influence, the process being described as follows:—

After preparing for the operation, he settled himself on the sofa, leaning partly on his elbow; and, pouring a very small quantity of chloroform on a handkerchief—certainly not more than thirty drops—he began to inhale very gently for about two seconds, then suddenly proceeded to inhale with the utmost energy, forcing inspiration to the fullest extent of the chest's capacity. After a few such inspirations, he fell back on the sofa, perfectly insensible. The operator had to make a very deep and (what would have been) painful incision, so as to include the base of the tumour. The patient never moved during the moment the operation was being done; and in an equally short time he was sitting up and chatting in his usual manner. The inhalation, operation, and perfect recovery, did not occupy more than thirty seconds.

The author had since then, as he says, employed the same method on himself and others with complete satisfaction, and he believes it has unequivocal advantages over any method hitherto known. In support of this view he quotes the following passage from one of Dr. Richardson's lectures:—

"It does not appear that the act of producing cerebral unconsciousness is ever a cause of danger to life; and, except in cases when the vapour is too irritating, we have little evidence to show that during the administration of chloroform there is any primary risk from injury done to the centres of the nervous system that govern respiration."

A New Function for Coroners.

A Bill has just been introduced into the House of Commons "to make provision for inquiries into the origin and circumstances of fires." Power is given to coroners of districts where fires may have occurred to make inquiries respecting their origin and character; that is, if a representation has been made to them by an officer of police, by the magistrates, or any persons interested in the premises where the fire took place, "that there is ground to believe such fire to have been caused or aggravated by the wilful or unlawful act or default of any person, whether known or unknown." The manner of conducting the coroner's inquiry is described in clause four of the Bill; and clause five provides that the coroners shall make annual reports to the Secretary of State of the circumstances connected with such fires as may have been reported to him. The Act is to apply to Ireland; but with the following exceptions and modifications.

The additional remuneration to be paid to a coroner in respect of his duties under this Act shall be paid, allowed, and borne in the same manner as his remuneration in respect of his ordinary duties; and the maximum amounts which may be presented for the payment of a coroner, under the provisions of the Act for the time being in force respecting coroners in Ireland, shall, in the case of coroners acting for the purposes of this Act, be *twice* the amounts respectively which may now be presented as aforesaid.

The provisions of this Act as to scales of payments to witnesses, and as to the disbursements of a coroner, shall not apply to Ireland; but the expenses of witnesses, and the disbursements and mileage of the coroner upon an inquiry held under this Act in Ireland, shall be paid, allowed, and borne as in the case of an inquest held by the same coroner on the death of any person.

Condurango.

At the meeting of the Clinical Society on the 9th February, Mr. J. W. Hulke read a paper on Cases of Cancer treated with Condurango in the Middlesex Hospital. The author and his colleague, Mr. Campbell De Morgan, were enabled by the present of a parcel of condurango bark by an American surgeon to begin in November last a second trial of this reputed remedy for cancer. When this supply ran short, the trial was continued with bark bought of John Bell and Co., and with a fluid extract very liberally placed at the author's disposal by its makers, Messrs. Bliss, Keide, and Co., of New York. After briefly noticing its natural history, and the physiological and therapeutic properties assigned to the condurango, the author proceeded to relate two cases of ulcerated hard cancer of the female breast, and one of rodent cancer of the face, in all of which the exhibition of the reputed remedy failed to modify favourably, or to retard the progress of the disease. The result of this trial confirmed the author's first one, made in August and September last, which showed that, as a remedy for cancer, condurango is absolutely inert. At the same meeting Mr. De Morgan also read a paper containing a report of three cases treated at the Middlesex Hospital, showing the uselessness of condurango; and he mentioned others that had come to his notice tending to prove the same thing. He considered it very important that the fact should be widely made known that this and other so-called remedies for cancer had really no effect on the disease, as statements of wonderful cures were inducing the public to put faith in them, and to waste time and money in their trial. Of the cases on which he had tried the medicine, two were advanced cancers of the breast, and one was uterine. The patients were suffering generally from the effects of the disease, and were considered fit cases on which to try the experiment. The medicine was given regularly and carefully in the manner directed. In no one instance was there the slightest improvement in the conditions of the local disease, which advanced at the same rate as before; neither was there any diminution of pain or discharge, or any change for the better in the characters of the ulcerations. There was not, moreover, any general improvement. For a day or two they thought they had a better appetite, but this was the mere transient change one always sees in cancer patients. None of the changes which were said to take place in the conditions of the urine or the perspiration had been observed. Mr. De Morgan's impression was that the downward progress of these patients had not been arrested for one instant by the agency of the drug.

An Example.

The Japanese Government, duly appreciating the valuable and gratuitous services rendered to them by the late Dr. Newton, R.N., have placed 1,000 silver *yen* at the disposal of H.B.M.'s Chargé d'Affaires, to be forwarded to England for the benefit of the relations of the deceased.

Important Changes in the Army Medical Department.

THE *United Service Gazette* stated lately that it was contemplated to transfer all regimental Medical Officers to the Staff, and that in future no Medical Officers would be gazetted to regiments. It now announces that the Royal Warrant that will be necessary to effect this and other alterations in the department is in print, and will shortly be issued. The 1st of April next will doubtless be the day fixed for the general transfer, and on and after that date the several surgeons and assistant-surgeons, now of regiments, will only be attached to them. With many Medical Officers this change will be very unpopular. Some have gone to considerable expense with regard to their regimental position, and we hear, at present, nothing about compensation to be paid on that account. On the other hand the *Gazette* announces to the long-suffering Assistant-Surgeons that their condition is now being discussed by the authorities, and that although nothing has as yet been decided, still a plan founded upon the general principles of the Indian Medical Service is likely to be adopted, that is to say, that after a given number of years, say ten or twelve, an Assistant-Surgeon shall become a Surgeon, not by promotion to a vacancy, but by simple service only, just as a Surgeon becomes a Surgeon-Major after twenty years' service. Several schemes have been propounded more or less feasible, but this, we think, is likely to find most favour with Mr. Cardwell, because it is not only that of his chief adviser in Medical questions, but it is also the most practical. It is understood that on the transfer of the regimental Assistant-Surgeons to the staff the opportunity will be taken to weed the department of its least efficient members, and that probably a reduction, eighty-six from the lowest grade, will take place during the next six months.

In its last issue, the *United Service Gazette* returns to the subject, and anticipates that disappointment will be felt that what it promised is not endorsed by a corresponding alteration in the Estimates for the ensuing year. The fact of the absence of change in the Estimates need cause no dejection to those Assistant-Surgeons immediately concerned, as our information was of too reliable a nature for us to doubt for a moment its authenticity; moreover, the scheme had been too recently propounded for it to have arrived at sufficient maturity for development in the Estimates of 1872-3. We have every reason to hope that before the summer arrives the decision of the authorities will have been obtained.

Prodigious Gall Stones.

AT a recent meeting of the London Pathological Society, Dr. Thorowgood exhibited, for Dr. Locke Johnson, two gall stones, which he removed from a female patient, æt. 67, and who suffered no inconvenience from their presence during her lifetime. They completely occluded the gall bladder; assumed its shape; were composed principally of cholesterine, and weighed at the period of removal, 580 grains, the larger of the two weighing 420 grains.

DR. BRISTOWE will lecture at the Royal College of Physicians of London, on March 6th, 8th, and 13th, at five p.m., "On Disease and its Remedial Treatment."

The Medical Council.

WE defer our notice of the meeting of the General Medical Council, in order to treat of its proceedings as a whole.

On Sleep and Dreams.

PROFESSOR HUMPHRY, F.R.S., at a late meeting of the Royal Institution of Great Britain, lectured on sleep. First of all he gave a brief account of some of the changes that take place in the tissues when their function is active, and explained that during this time a slight deterioration of structure takes place, which, affecting the voluntary system—the muscles and the hemispheres of the brain—causes the sense of tiring, and necessitates a period of rest for the restoration of the tissue to its former condition In the case of the muscles this rest is provided for by quickly alternating periods, of action and repose. But in the case of the brain, the actions upon which consciousness depend cannot be frequently suspended. Their continuance is needed for the safety of the body during long periods, through the whole day for instance; longer periods are therefore required for repair.

The learned professor explained that the upper regions of the brain are those which minister to consciousness and volition—the intellectual operations—that the functions of these regions not only can long be suspended without interfering with the action of the lower parts of the brain which are more immediately necessary to life, but that they are very easily suspended, slight causes, such as a jar or a shock, or an alteration in the blood current, being sufficient to stop the action of these parts, and deprive the person of consciousness. The spontaneous stoppage of their action, consequent on the slight deterioration of their structure from the continuance of their functions during the day, is the proximate cause of sleep during the night; the periodic recurrence of sleep is in accordance with the periodicity observed in several of the nutritive functions, as in many other operations of nature.

Professor Humphry regarded dreams not as a necessary attendant on, or feature of, sleep, but rather as the result of an abnormal condition. In the natural state we should pass from wakefulness to complete unconsciousness, and *vice versâ*, quickly, almost instantaneously; and many persons habitually do so. But the transition period is sometimes prolonged, and stages are observable. The first thing that occurs is the lowering or cessation of that control over the mental processes which is the highest of our powers, the one requiring the greatest effort and the one most easily lost. In this condition the thoughts ramble unchecked, chase one another confusedly over the mental field, and give rise to all sorts of incongruities of the imagination. At the same time being unrestrained, they are excited, and evince efforts of memory and even of combination which in the regulated state of wakefulness they are quite incapable of. In this way the images of persons and places, of events and items of knowledge long forgotten in the ordinary state, are recalled with distinctness; and we fancy that new information has been acquired, when it is only forgotten facts that are recalled. He did not agree with the physiologists who conceive that dreaming depends upon an inequality in the condition of different parts of the brain, some being excited or wakeful, while others are quiescent or asleep. He rather took the view that all the parts of the cerebral hemispheres combine in each of the efforts of control, consciousness, memory, and other mental acts, that all suffer alike from these effects, alike need the restoring changes which take place in sleep, and together, *pari passu*, pass through the stages on the way to and from sleep in which dreaming, sleep-walking, &c., occur.

Secret Poisons.

It is now upwards of twelve months since we adverted to the circumstances attending sudden deaths with all the symptoms of asphyxia, and quoted an alleged case from the *Canadian News*, "of the receipt of an anonymous letter that contained some poisonous substance, which its reader having inhaled, fell down and died," and at the same time sought some confirmatory evidence from such of our readers in whose minds any suspicion of foul play might have arisen when investigating cases of sudden death, and also what were the nature of the symptoms.

In answer to these suggestions we received a communication, stating that these unearthly practices were not unknown in Italy (being to all appearance *heart disease*), and were even now suspected in this country, and believed to be quite as rife as in the worst times of the Medici. A reference was at the same time given to Oliver Goldsmith's Letter No. 106 in *The Citizen of the World.*

As more than one of our contemporaries afterwards threw some discredit on these suspicions, in reply, one of our contributors on the 17th January last, "Vindex" referred to the use of *tophayne* in India by the Thugs with such deadly certainty, that they could calculate accurately its effect according to the strength with which it had been compounded and administered, and also cited Sir Walter Scott's notices in the Appendix G., title Dr. Julio, at the end of "Kenilworth," quoting Parsons the Jesuit's "Leicester's Commonwealth," from which we gave only one short extract from amongst many, disclosing the skill of this Italian poisoner in the sixteenth century.

We have since been informed that the *Saturday Review* has recently written upon the subject, but without seeking to answer so specious an antagonist, whose Jesuitical tendencies are no secret; we, however, feel bound, in defence of that to which we have already afforded publicity, to give a few extracts from the *Daily Telegraph* of Wednesday, 28th February last, under the head of "Death at the Carnival," from their own correspondent at Rome, dated on the 16th February last. This letter thus commences:—

"*In the midst of life we are in death,*" and then proceeds to state that, "No more striking illustration of this text has been seen, than that afforded by the death of General Cugia, first aide-de-camp to Prince Umberto. The Miccoletti are lighted on Shrove Tuesday at nightfall, that is to say, after six o'clock; at seven o'clock all the lights are extinguished, and the Carnival is practically concluded. Well, General Cugia was in a balcony of the Hotel de Rome, in the company of the Prince, and was for some time as busy as any one in extinguishing the tapers of his neighbours when he suddenly felt indisposed, and requested the permission of his Royal master to go home. On his way to the Quirinal he must have rapidly become worse, for, when arrived there, he had not even strength enough to go up to his apartments, but was obliged to be led into the concierge's room, where he breathed his last at a quarter before seven o'clock. To take part in all the boisterous fun of the Miccoletti, to be taken ill, to go home, and to die, before even those little tapers have ceased to live, is a fate too startling even for this land of inexplicable events. . . . . . He was the constant companion of Prince Umberto in all the drives which the heir to the Italian Throne delights to take in his small Victoria on the Pincio, or in the Borghese Gardens; so that the General was one of the best known men in Rome."

* * * * * *

After giving a full description of the effect of this sad event in the capital of Italy and of the funeral *cortége*, their correspondent states that amongst the pall-bearers were the Minister of War and Prince Umberto, who walked with the procession "amidst a tremendous shower of rain, which sent all the bystanders flying, whilst the chanting Monks raised their enormous blue umbrellas to protect their already hooded heads, and the mounted guardsmen hastened to seek the shelter of a neighbouring courtyard. But the Heir to the Throne marched steadily, slowly on, unmindful of the rain, mindful only of the companion whom he was taking to his last home," and then adds—"I must not conclude without noticing a statement made by this morning's *Capitale*, that in the course of Tuesday afternoon a bouquet was lifted down to the Royal balcony from an upper floor, and that a paper addressed to the Prince was attached to it. It fell into the hands of General Cugia, who read the paper without presenting it to the Prince, and seemed much startled by it. At the window from which the bouquet was lowered stood a priest, who, it was remarked, looked confused when the bouquet was taken up by wrong hands. Ergo, says the *Capitale, the General was killed by poison intended for the Prince.* Now I was laughing over this story this morning when I was reproved by an English gentleman, who has lived in Rome some quarter of a century, and who said, '*Oh, such things are not uncommon here.*' A monsigniore told me recently that there had been many cases of apoplexy lately, *and that there would be more.* Now, I offer no opinion on this matter. It seems to be not unreasonable that the General should have died, as he is said to have died of aneurism of the heart. But what a state of society is disclosed by the mere fact of such a suspicion gaining credit! The Liberal journals discern in the sudden death of a friend the hand of the poisoner; and the Clerical papers do not blush to attribute the taking away of a good Monarchist to the '*finger of God.*'" *Veritas visa et mora falsa festinatione et in certis. Valescunt.*

A frightful accident is reported from Antwerp. A house fell on Friday from some inexplicable cause, burying all the inmates, about twenty of whom have been removed from the *débris* lifeless.

A shark was recently captured at St. Albans, near Sydney, and upon opening the body a human head, and the upper portion of the trunk was discovered therein.

Fifteen persons were poisoned last week through partaking of a rice pudding in which a quantity of white arsenic had accidentally been mixed with ground rice.

The New Public Health Bill is announced for presentation to the House of Commons by the Government on the 14th instant. It is stated to be a most important and comprehensive measure.

At the Pathological Society of London on February 20th, Mr. John Hilton, F.R.S., who was in the chair, intimated to the Society that the Council had recommended that portions of certain evenings should be set aside for the discussion of abstract questions. Any member of the Society might make a prearrangement with the secretaries for the exhibition of specimens or drawings illustrative of some particular point, and due notice having been given beforehand by means of the usual channels, there could be little doubt that very valuable discussions would result from the observance of this plan. The time had certainly arrived when the Society might make use of the enormous amount of valuable material accumulated in the volumes of its Transactions, and attempt to deduce therefrom important generalisations.

Mr. Alfred Haviland's next lecture on "The Geographical Distribution of Scrofula in England and Wales," will be delivered in the theatre of St. Thomas's Hospital to-morrow (Thursday) at 8 P.M.

Dr. Holt Dunn is a candidate for the Coronership to the City of London. We have on former occasions expressed ourselves strongly in favour of members of the Profession to fill these posts, and hope a Medical candidate will be successful on the present occasion.

◆

SCOTLAND.

Sir Robert Christison, Bart.—The jubilee of Sir Robert Christison, as a professor in the University of Edinburgh, was celebrated on Friday the 24th February. The members of the University Rifle Volunteer Corps, whose Captain, Professor Christison has been since 1859, presented him with a sword of honour, the ceremony taking place in the college quadrangle. The enthusiasm exhibited by the students and the public, who assembled in large numbers to witness the ceremony, was very great. Immediately afterwards Sir Robert received an address from the Edinburgh University Club of London, which was presented at the Library Hall. Professor Balfour introduced the deputation which consisted of Dr. Duckworth, Dr. Davy, and Dr. Halley. In the evening he was entertained to dinner in the Douglas Hotel, the Lord Justice General, Chancellor of the University, occupied the chair; and the croupiers were Sir W. Stirling Maxwell, Bart., Sir Alexander Grant, Bart., the President of the Royal College of Physicians, the President of the Royal College of Surgeons, and the Presidents of the Faculty of Physicians and Surgeons, Glasgow. Upwards of 250 sat down to dinner. It has never, we believe, been the fortune of any other man to receive such almost overwhelming expressions of hearty sympathy, respect, and affection as have so deservedly fallen to the lot of Prof. Christison.

The Edinburgh University Court have intimated to Miss Jex Blake that the medical education they afford to the lady students does not give any legal qualification to practice.

Lord Lytton has declined the Lord Rectorship of St. Andrew's University.

◆

Literature.

AITKEN'S MEDICINE (a).

A **manual** of the "Science and Practice of Medicine," which in fourteen years has reached a sixth edition, has passed beyond the aims of the ordinary reviews of weekly Medical journals. Especially are we reminded of this as we remember that other editions have uniformly been commended in these columns, although in nearly every instance by different critics. The present Reviewer, who has not previously expressed his opinion of this work, finds that those who have preceded him in the task have almost exhausted the phraseology of praise for Professor Aitken's learned work, which has also been highly lauded by numerous other journals both in this country and America as a thoroughly reliable and complete treatise on the practice of medicine. We propose, therefore, merely to record some of the points of this edition, and to add our testimony to the real value of the work both to students and practitioners. These two volumes are a library of themselves. They give a general view of the theory and practice of medicine in accordance with physiological and pathological principles and the present state of scientific knowledge.

The nomenclature now adopted is that of the College of Physicians, and the work is now arranged in the order of that classification. This plan we must approve of.

This nomenclature may now be considered official, and it is highly desirable that the system of naming diseases should be more uniform. Perhaps in the next generation of medical men this desirable reform may be accomplished, as Dr. Aitken has thrown his valuable influence into the right scale in this matter.

Among the improvements most prominent are the temperature diagrams, which have been cut on a new model. Dr. Aitken was the first to introduce these into a textbook of medicine, and it is very pleasant to see him thus determined to keep pace with clinical progress.

The portion of the work devoted to "Disorders of the Intellect" has been revised by Dr. Blatherwick, of Netley Lunatic Hospital, and the author expresses his thanks to that gentleman for valuable notes and practical suggestions, as he does also to other authorities who have kindly lent him their aid to perfect the work. Foremost and most important of these is Professor Balthazar Foster, of Birmingham, to whom the author expresses gratitude for his help in the section on "Diseases of the Heart," and in relation to the sphygmograph. It is well known that Professor B. Foster is an authority the student may safely follow, and his sphymographic tracings are a most valuable addition to these volumes.

Dr. Mackenzie has revised the chapter on "The Laryngoscope," and Mr. Lennox Browne has executed for it new woodcuts. Dr. Anderson, of Glasgow, has done the same for "Parasitic Skin Diseases."

There are many other points that might well have detained us; but sufficient has been said to show that the author has earnestly worked to keep his manual worthy of the success it has obtained. We have only to add that the publishers have brought out the volumes in a manner which proves that they too are determined to keep pace with the times.

◆

YEAR-BOOK OF PHARMACY (a).

This goodly volume, which appears to be the second of the series—but the first of which did not come under our notice—comprises abstracts of papers that have appeared on "Pharmacy," "Materia Medica," and "Chemistry," between July 1, 1870, and June 30, 1871, edited by Mr. Charles Wood, F.C.S., to which is added the "Transactions" of the Pharmaceutical Conference of 1871, of which at the time we gave some brief account, edited by Professor Attfield.

We have been much interested in both divisions of the work, and can bear testimony to the result as one with which both editors have a right to feel satisfied. The volume is, indeed, a worthy one; and we are pleased to observe that the Pharmaceutical Conference numbers nearly 2,000 members, who are, of course, the *élite* of the pharmaceutists in the county.

In the introduction we find a condensed summary of the most remarkable additions to pharmaceutical progress of the year. The volume possesses that important part of a book of reference—a good index. The "Year-Book" should be found in all medical and pharmaceutical libraries.

(a) "The Science and Practice of Medicine." By William Aitken, M.D., Professor of Pathology, Army Medical School. Sixth Edition. 2 vols., illustrations. London, 1872. Charles Griffin & Co.

(a) "Year-Book of Pharmacy,"—1871. London: J. Churchill & Sons.

THE VACANT IRISH SURGICAL BARONETCY.

The aroma of recent medical honours conferred in London and Edinboro', still pervades the atmosphere of the Profession in Ireland, and no little disappointment is felt that medicine and surgery in that country should remain without royal recognition. The services which Sir William Jenner and Sir William Gull have rendered to the nation might justly, one would think, be considered worthy of some recognition, not in the individual, but to the Profession which they represent; but Ireland has louder claims to such a distinction on the ground of being alone left without a surgical baronet. Mr. Adams's claim to receive such an honour is unchallenged and indisputable, and failing his acceptance of it, Mr. Porter's rank in the Profession entitles him without doubt to the second claim on the consideration of Her Majesty.

With recipients so worthy at hand, there can be no just reason for keeping back the compliment to the Profession in Ireland, and we trust that the existing feeling of undeveloped jealousy will not be allowed to ripen into angry hostility.

Correspondence.

ON THE INFLUENCE OF ERGOT IN MIDWIFERY PRACTICE.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—I beg to say I was somewhat grieved to learn by the last number of the Medical Press that Dr. Sheil has become very irate by my letter of the 24th ult. I can assure him I did not mean to ruffle in the least degree the natural suavity of his feelings, and that my only motive was to discuss *calmly* a subject of some interest to the Profession—I mean its junior members. And I repeat that in doing so, I thought it would be conducted in a *gentlemanly* manner, and that there would be no descent from the sublime to the ridiculous.

You will, I trust, notwithstanding the doctor's (perhaps I use an "unwarrantable liberty" here) imperious mandate—"Dismiss your printer at once, sir (surely it must be an error of his), &c." Not at all, my dear doctor (perhaps another unwarrantable liberty), the words you quote are mine; I adhere to them, I advisedly used them, and I never try to make a good case out of a bad one by any coating of varnish—give me a little space in your journal, though I do not make use of such trite and sycophantic phrase as "a hitherto unimpeachable journal," I do not arrogate to myself the whole space you so liberally assign to correspondents as Dr. Sheil would seem to do, but merely as a subscriber to enjoy an equal privilege with him or any other. He must indeed have been very jaundiced—I trust it has passed off by the "hearty laugh," or I would fraternally suggest to him to consult *the* doctor in due time—when he has recourse to such an expression as "like the inevitable clown in the circus."

But to return to the subject matter of discussion. He does not say a word about the quotation in mine of the 24th ult., from an eminent work on "Therapeutics," and also from an eminent teacher of Midwifery, Dr. Beatty. Now for more authorities on the use of ergot. Neligan says, "It is now very generally admitted that the administration of ergot of rye during labour endangers the life of the fœtus, and that this depends on the poisonous action of the drug, as evidenced by its effects on the action of the heart both of the mother and child, &c."—"dose of ethereal tr. ʒss. ad. ʒj." So much for what Dr. S. is pleased to term my Homœopathic treatment.

Tyler Smith says of ergot, "On account of the spastic contraction of the uterus caused by this medicine, which interferes with the utero-placental circulation, and perhaps also from some specific influence upon the circulation of the fœtus, the state of the child should always be watched, while the mother is under the influence of ergot, and delivery be completed by the forceps, if the action of the fœtal heart is quickened to any great extent." Now, I hope Dr. S. will learn the nullity of his dogmatic and reckless assertion where he observes, "But to return let me inform Dr. McK. of a fact of which he is either seemingly or wilfully ignorant (I am neither), namely, that the utmost ill effects produced by an ordinary dose or repeated doses of ergot (oh!) is sometimes, not always, a little nausea, or sickness of stomach, which soon passes off; its power for evil on the fœtus—when the uterus is not excited to action by it—is absolutely nil." Strange! wonderous strange! or he must be by odds a far more eminent authority than the hitherto admittedly eminent men, Neligan and Tyler Smith. Now I desire to give Dr. S. a *wrinkle* on the treatment of semi-asphyxiated children, taken from the very excellent work of Cazeaux, on "Midwifery." In his chapter on Labour, wherein he speaks of the treatment of the child in a feeble or diseased state he (Cazeau) says, "When the child is born with a general injection of the capillaries of the face or trunk, when in short it presents the characters of the state formerly termed Apoplexy, it is evident that the first indication is to relieve the engorgement of the head and lungs, which is done by *promptly cutting* the umbilical cord (which I had done, but Dr. S., as an eminent authority, would not), and allowing a few spoonfuls of blood to escape, &c."

Further on he (Cazeau) says, "According to Marshall Hall, the best plan is to sprinkle the face and body of the child vigorously with *cold* water, immediately after which it should be immersed in a *warm* bath, &c."

So much again for his notions of "Hydropathy."

In another part he asks, "Where in all the world, I would ask, should the *uterus be* if not *between the head of the child and pubis!*" (The underlining is mine.) Well, it might be in any part of the world, but certainly not between the head of the child and pubis, except in some of those exceedingly queer "freaks of nature" with which he seems to be familiar.

In the conclusion of his letter he becomes very egotistical, when, as he says, he has performed all those fine operations, except the "Cæsarian, often single-handed," &c. But I think he must be napping while penning it; nor is it to be wondered at, for as great men before his time are said to have been in the somnific mood; for instance, Homer.

I am, Sir, yours, much obliged,
John M'Keogh, L.R.C.P.

Thurles, 23rd Feb., 1872.

[We consider that this correspondence has gone far enough, and must decline further letters on the subject. Dr. Sheil must have credit, of course, for all he would say in reply, if we could give him space.—Ed. M. P. & C.]

NOTICES TO CORRESPONDENTS.

Victim.—This Correspondent asks us if we know anything of the "Professional Standing" of Dr. Watson, F.R.A.S., 1 South crescent, Bedford square, W.C. In reply, we extract the following from Mr. Courtenay's work, "Revelations of Quacks and Quackery":—

"Hill *v.* Watson, *alias* Rackey.—One residence in their case equally does double duty, like the residence of the former worthies (Henry, James, and Hammond). Thus, the Berkeley House, South crescent, Russell square, is also known as No. 1 South crescent, Bedford square. The qualification of governor of the Lock Hospital is possessed by every subscriber of a certain sum to that useful institution." To this we would add, that Watson, Hill, Smith, James, Hammond, or whatever other name they go under, are amongst the most notorious scoundrels who infest the metropolis.

Dr. C. B. T.—It will appear in another form.

Postal Cards.—It has been decided by Her Majesty's Government, that in future *private cards* with written communications on one side, and the address with a half-penny stamp affixed on the other, will be allowed to pass through the post; and that the restrictions hitherto imposed against the more general adoption of this useful channel of communication shall be removed. We heartily wish the Government would extend their revision to the prohibition to stitch newspapers; there cannot possibly exist any reason why so absurd a clause should stand, and there is every reason why it should be removed.

Erratum.—The heading of Dr. Jacob's lecture on "Eye Disease," which appeared in our issue of Feb. 14, contained two clerical errors. The author's qualification in medicine stated as M.D.Ed., should have been "M.D.Dub. Univ.," and the prefix *ex* should have been attached to "Ophthalmic Surgeon to the City of Dublin Hospital."

Eye Diseases and Injuries.—The continuation of the series of lectures on this subject, by Dr. Archibald Hamilton Jacob, is unavoidably held over until our next.

Erratum.—The Contagious Diseases Acts.—In the letter signed J. Birchenall, M.R.C.S., in our last number, at page 196, line 13, for "untimely" read "intimately."

APPOINTMENTS.

Barry, J. C., L.K.Q.C.P.I., Medical Officer, &c., for the Ballyduff Dispensary District of the Lismore Union, Co. Waterford.

Bryan, F. C., M.R.C.S., Assistant House-Surgeon to the Sheffield Infirmary.

Edwards, J. E., M.R.C.S.E., Assistant Medical Officer to the North Wales Counties Lunatic Asylum, Denbigh.

Edwards, Mr. H., House-Surgeon to the Carnarvon Infirmary, Bangor.

Fitzgerald, F. C., L.K.Q.C.P.I., Medical Officer for District No. 4 of the Holsworthy Union, Devon.

Hawthorne, J., M.D., L.R.C.S.Ed., Medical Officer to the Workhouse and Fever Infirmary, Banbridge Union, Co. Down.

Johnston, R., M.R.C.P., L.R.C.S.I., L.M., Resident Surgeon to the Nottingham Dispensary.

King, T. R., M.D., Assistant Medical Officer to the Newcastle-upon-Tyne Borough Lunatic Asylum.

Laird, S., M.D., M.R.C.P., Medical Officer to the Isle of Man Hospital.

M'Caw, J. D., L.R.C.P.Ed., Resident Physician to the Notts. Dispensary.

Petit, J., L.K.Q.C.P.I., L.R.C.S.I., Medical Officer to the Workhouse of the Dunshaughlin Union, Co. Meath.

◆

Marriages.

Vatcher—Lankester.—On the 28th ult., at the Parish Church, Hampstead, the Rev. J. Sidney A. Vatcher, B.A., Old Alresford, Hants, to Marion, second daughter of Edwin Lankester, Esq., M.D., F.R.S., coroner for Middlesex.

Millar—Ibbetson.—On the 2nd March, at St. Matthew's, Bayswater, Robert Millar, M.D., Surgeon-Major (retired) Bombay Army, to Annie, widow of the late Capt. F. J. Ibbetson, 2nd Dragoons.

◆

Deaths.

Anderson.—On the 25th ult., Chas. Abercrombie Anderson, M.D., C.B., Inspector-General of Hospitals and Fleets.

Firth.—On the 24th ult., at Union road, Rotherhithe, Joseph Thos. Forbes Firth, L.F.P. & S.Glas., aged 46.

Haire.—On the 27th ult., at Kildare terrace, Bayswater, Thomas Haire, M.D.

Hunt.—On the 28th ult., at Dorset square, London, Caroline Stafford, daughter of Thomas Hunt, F.R.C.S., aged 21.

CLERICAL, MEDICAL AND GENERAL
LIFE ASSURANCE SOCIETY.

DIRECTORS.

CHAIRMAN.—Right Hon. JOHN ROBERT MOWBRAY, M.P., D.C.L., Mortimer, Reading.
DEPUTY-CHAIRMEN. { WILLIAM BOWMAN, Esq., F.R.S., 5 Clifford street, Bond street.
Sir CHARLES LOCOCK, Bart., D.C.L., F.R.S., 26 Hertford street, May Fair.
HENRY WENTWORTH ACLAND, M.D., F.R.S., Oxford.
LIONEL SMITH BEALE, M.B., F.R.S., 61 Grosvenor street.
PATRICK BLACK, M.D., 11 Queen Anne street.
CHARLES MARCH DEANE, Esq., Banker, Winchester.
ARTHUR FARRE, M.D., F.R.S., 12 Hertford street, May Fair.
Sir WILLIAM JENNER, Bart., K.C.B., M.D., F.R.S., 63 Brook street.
Rev. JOHN EDWARD KEMPE, M.A., St. James's Rectory, Piccadilly.
GERARD WOLFE LYDEKKER, Esq., M.A., The Lodge, Harpenden, Herts.
The Viscount MIDLETON, Peper Harow, Godalming.
Rev. JOSEPH MOORE, M.A., Buckland, Faringdon.
Sir JAMES PAGET, Bart., D.C.L., F.R.S., 1 Harewood Place, Hanover square.
Rev. FREDERIC JAMES PARSONS, B.D., Selborne, Alton, Hants.
GEORGE HENRY PINCKARD, Esq., Combe Court, Godalming.
Sir FREDERICK MARTIN WILLIAMS, Bart., M.P., Goonvrea, Perranarworthal.

ACTUARY AND SECRETARY.

GEORGE CUTCLIFFE, Esq.

ASSISTANT ACTUARY.

BENJAMIN NEWBATT, Esq.

NINTH BONUS MEETING, January 4th, 1872.

The following are Extracts from the Report of the Directors:—

1.—PROGRESS OF THE SOCIETY IN THE BONUS PERIOD.

"1. AS TO INCOME:

The new Assurances were 2,150 in number, for an aggregate sum of £1,356,303, at premiums amounting to £44,664 per annum,—results which, viewed in relation to the depressed condition of Life Assurance during much of the period, cannot be regarded as other than satisfactory.

The Yearly Revenue was increased by over £21,000 per annum, and reached £236,563 on the 30th June, 1871.

The Interest yielded by the whole of the Funds, whether invested or uninvested, was £4 5s. 0d. per cent. on the average of the entire period, being fully 3s. per cent. more than that realised in the previous period. This increase was obtained not only without loss but without the smallest impairment of security.

"2. AS TO OUTGOINGS:

The Claims which accrued by the death of 795 persons, assured by 977 Policies, amounted to £646,481. . . . . The mortality . . . . was very favourable to the Society, the payments having been below those estimated by fully £85,000, and the deaths which occasioned them fewer by 92 than the number expected.

The Expenses incurred in conducting the business, always moderate and well within the provision made for them in the premiums, were fractionally less than in the previous period, and fell below 7½ per cent. on the Revenue.

It is thus seen that side by side with uniform success in the transactions of the Quinquennium, there was continuous growth in the resources and magnitude of the Society, which consequently stood, at the closing of the books, on a broader basis than at any former time."

2.—FINANCIAL POSITION OF THE SOCIETY ON JUNE 30th, 1871.

"The subsisting Assurances on the 30th June were 8,679 in number, assuring with their Bonus additions, the sum of £5,445,028.

	£	s.	d.
The Assurance Fund at the date of Valuation was	1,826,458	10	9
And the total calculated Liability	1,477,179	17	3
Leaving a surplus of	**£349,278**	**13**	**6**

Deducting therefrom the permanent Reserve Fund of £50,000, pursuant to sec. 32 of the Society's Special Act of Parliament, there remains to represent the profit of the 5 years the large sum of £299,278 13s. 6d., an amount equal to 26 per cent. of the total Revenue from all sources during the 5 years, and exceeding by £59,831 6s. 5d. the surplus of any previous Quinquennium.

This Surplus is matter for hearty and unmixed congratulation, and justifies the preference shown by the Board for a well-selected business tending to profit. It must, however, be remembered that although owing in the main to ordinary recurring causes, and to sources of profit having every prospect of permanence, it is, nevertheless, certain that its unprecedented enlargement is due to a condition of mortality favourable beyond previous experience, to be probably compensated under the law of averages by an increase of deaths hereafter beyond those allowed for in the calculations.

Deeming it prudent to provide for such a contingency, the Directors have, under the advice of their Actuary, set aside the sum of £25,000 for this purpose. Of the remaining £274,278 13s. 6d. they now recommend the division of £270,000, a sum greater by £33,000 than any previously divided, and sufficient to give to the Shareholders £9 a share, and to the assured the largest bonus ever allotted to them."

3.—RESULTS OF THE DIVISION.

"Of the sum now to be divided, five-sixths, or £225,000, will fall to the Assured, and will produce a reversionary addition to the Policies of £323,871.

This Reversionary Bonus will average 49 per cent., or vary according to age from 34 to 89 per cent. on the Premiums received in the Quinquennium on all the Policies amongst which it will be distributed.

The Cash Bonus, which is the present value of the Reversionary Bonus and therefore the true measure of the allotment, will average 29 per cent. on the like payments, as against 26 per cent. at the last Division, and 28 per cent. in 1862, which was the highest previous percentage. No comment can illustrate better than this comparison the merits of the present Division."

The next Division of Profits *will take place in January*, 1877, *and Persons who effect* New Policies before the end of June next *will be entitled at that Division to one year's additional share of Profits over late Entrants.*

The Report above mentioned, a detailed account of the proceedings of the Bonus meeting, the returns made to the Board of Trade, and every information can be obtained of

GEORGE CUTCLIFFE, ACTUARY AND SECRETARY,
18 *St. James's Square, London, S.W.*

N.B.—A Fee of One Guinea is paid to the Medical Attendants of all Persons proposing to Insure.

LECTURES ON DERMATOLOGY.

Delivered in the Royal College of Surgeons of England, in February, 1872, by

Erasmus Wilson, F.R.S.,

Professor of Dermatology to the Royal College of Surgeons of England.

LECTURE III.

I am afraid, Sir, that you, and the rest of my audience, have fair ground for accusing me of repeating with reference to this or that disease—that it is *one of a deeply interesting nature and highly important to be known*, but if I have said this before in regard to bygone subjects I must echo it again in connexion with Herpes, and the more so because, although not so common as eczema, it comes before you more frequently in daily practice. And I take this opportunity of making a remark bearing upon the question of numerical statistics. The dermatologist in the midst of a community, from the reputation attaching to the nature of his practice, is in the position of having every example of chronic cutaneous disease, such as eczema, brought under his notice in the course of time. But with such an eruption as herpes, which is regular and brief in its course, and often very trivial in its manifestation, the numbers which reach him will be comparatively few. Hence it is not in his note book, however carefully kept, that we must look for the exact truth in reference to the frequency of disease; and, therefore, I say, that herpes, although undoubtedly less common than eczema, will probably come under your notice more frequently than the latter disease.

In a few words it may be said that herpes is a cluster of vesicles, ranging in size between a pin's head and a pea, developed on an erythematous base; for the most part unilateral in distribution and limited in extent to the district supplied by a single nerve or by two or three contiguous nerves. This definition is illustrated in the drawing No. 120, and in the model 121 representing herpes zoster or herpes intercostalis. In the former of these the eruption is seen in its characteristic progressive stages, namely:—as nascent vesicles clustered on an erythematous base, as fully developed vesicles, discrete and confluent, transparent and opaque, colourless, yellowish in different degrees, or purplish, and finally as incipient scabs.

In the model 121, the eruption covers a greater extent of surface than in the former case, occupying about the fourth, fifth and sixth intercostal spaces and extending from the region of the posterior border of the scapula to the ensiform cartilage. The blotches are continuous throughout the whole extent of the eruption, but a few isolated blotches of small size and a few scattered vesicles may be seen along the upper and lower boundary of the patch. The nipple is completely surrounded, and the illustration may be regarded as a severe example of the disease. The patient was a man, 60 years of age; he remained in hospital for ten days and left much improved. He was under the care of Lailler, and was treated by the application of an alcoholic solution of perchloride of iron, one part in five.

Herpes zoster may be very fairly taken as the typical form of herpes; its subjective designation being derived from its frequent occurrence around the waist of the patient, hence its name zoster, a belt, and zona a girdle, and its latin synonym cingula, with the popular corruption of cingula, namely, shingles. If we were in search of an illustration of the identity of disease in modern times with that of an ancient period we should find it in zoster. Zoster has evidently always retained the same signification and awakened the same prejudices. The duality of the nervous system explains the well known fact that zoster is limited to one half of the body; and the extreme improbability of the development of the circle complete, no doubt suggested the aphorism attributed to Pliny, "Zoster appelatur, et enecat, si cinxerit." This aphorism of Pliny has become a popular belief amongst ourselves, and the dread of the disease is greatly relieved when it is found to confine itself to its accustomed limit, namely, one-half the circle of the waist.

Next to its obedience of the neurotic law of occupying only one half of the waist without completing the girdle, the point most worthy of our attention is its development in little blotches, which in fact, correspond with small branches and twigs of the cutaneous nerves, and if we call to mind the distribution of the intercostal nerve with its cutaneous branches, we have the key to the explanation of the exact seat of manifestation of the hyperæmic blotches on which the vesicles are developed and undergo their succeeding changes. Thus, a painful sensation of heat may be experienced somewhere near the linea alba; the anatomist will tell us that it is there that the intercostal nerve gives off its anterior cutaneous twigs, and it is in the small district of skin supplied by those nerves that our patient becomes aware of a burning and tingling which first of all direct his attention to the spot and announce the beginning of the eruption of shingles. In a very short time, however, he feels a similar sensation in the neighbourhood of the spine; now, the posterior cutaneous nerves are communicating their sense of grievance to the skin; and, at about the same time or immediately after, the integument supplied by the middle cutaneous nerves becomes similarly affected. The original blotches are consequently isolated and the space between them is shortly after filled up by other patches and scattered vesicles, all evincing the same phenomena objectively and subjectively. In the lithographic drawing the isolated position of the blotches is maintained; but in the model a considerable number of blotches have become confluent, and the inflammation of the skin is consequently diffused, more so in fact than we usually find to be the case. Again, if we take into consideration the breadth of the eruption in both these cases we arrive at the conclusion that more than one intercostal nerve must be involved in disorder; in the drawing there may probably be two, and in the case represented by the model, perhaps three or even four.

The local history of herpes is pretty much the same in every instance of its occurrence, and may be stated as being either slighter or more severe. If you have ever, and who has not, had one of those little burning and throbbing inflammations of the lip which are the common sequel of a feverish cold, you have experienced, on a very small scale and in a very mild degree, the operations of herpes. First, there is heat, burning, and throbbing, then there is swelling, next, two or three small vesicles appear on the surface, and in spite of every effort you may make to check its progress, the annoyance is prolonged for a week or ten days.

So, of the much larger blotches on the skin of the trunk of the body appertaining to herpes zoster, a number of red puncta may be seen in the skin, these in a very short time become glittering vesicles, filled with a transparent and colourless lymph, they grow and enlarge to the size of small peas, then the lymph becomes lactescent and opaque, subsequently yellow from the development of pus, and sometimes purple from the presence of blood; next they begin their retrograde stage—they collapse, they shrivel, they shrink, and finally they dry up into small, hard, amber-coloured scabs, deeply embedded in the skin, and retaining their hold for some time before they fall off, leaving a pitted mark of variable depth and size, generally so complete that it remains as a permanent white cicatrix for the rest of life.

This pathological process is not very dissimilar to that which we have already studied in relation to pemphigus, and the variations pointed out in respect of the latter eruption are equally applicable to herpes. A difference, however, is palpable—herpes is the consequence of a nervous shock, and not the consequence of a constitutional disorder or cachexia, moreover, it obeys an orderly course which may be estimated by days, ten to twenty in number, and pursues a regular succession of lesions, namely, hyperæmic congestion, exudation of lymph, vesiculation, pustulation, encrustation, and cicatrization, and then finally ceases without a prospect of relapse, and without derangement of the constitutional health.

Some of the specimens before us, and especially the plaster casts, numbered 123 to 127, illustrate admirably the distribution of the eruption in isolated blotches, the number and figure of the vesicles developed on each blotch, the distension of the vesicles, their occasional coherence and confluence, and the dense and embedded scabs which mark the completion of the retrograde process.

The wax cast No. 122 exhibits a scattered eruption of herpes affecting the arm, *herpes brachialis.*

The plaster casts, Nos. 123 to 126, mark the course of an example of *herpes cruralis.* The eruption occupies the thigh, and the casts show the daily progress of the blotches and vesicles. The history of the case also is characteristic:—A boy, 15 years of age, was chilled by sitting on the grass on Good Friday, April 10, 1846; the next day he had severe pain over the whole of the front part of the thigh, which was attributed to rheumatism. On the evening of Saturday a blush of redness in patches was apparent on the skin; on Sunday, minute vesicles in clusters were perceived here and there upon the red patches. The vesicles soon became distended with a transparent and colourless fluid and reached their full size, looking towards evening like so many pearls. On Monday, some of the vesicles were already becoming shrivelled and had a purplish hue, while others, fully distended, possessed a rich grape-yellow tint. On Tuesday, all the vesicles were on the decline, with the exception of a few tardy clusters, which were now attaining maturity. On Wednesday, the fourth day of the eruption, the greater part of the vesicles had dried up into reddish-yellow wrinkled scabs. On succeeding days the scabs became gradually darker and harder, and were closely embedded in the skin; by Saturday a few only of these scabs remained; and on Sunday, the day of completion of the week, traces only of the eruption remained.

No. 127 is a very striking plaster cast of herpes cruralis, situated at the upper part of thigh in the inguinal region. The blotch of eruption is solitary; it is oblong in figure, and displays the erythematous base as well as the cluster of vesicles, the hyperæmic base being slightly elevated.

These specimens inform us as to the fact, that no part of the integument is free from the invasion of herpes; that it may occur upon the face, upon the neck, on the shoulder and arm, around the waist, and upon the flank and lower extremity, and its relations to the nerves of those regions is so obvious, that it has received names conformable with the chief trunks which supply the different parts of the skin. Sometimes it makes its appearance and disappearance without other pain than the mere local suffering in the skin; sometimes it is ushered in with neuralgia, and is mistaken for that painful affection, until the eruption is developed, and, at other times, it ends with neuralgia, and the neuralgia is prolonged for many months and even years. The neurotic relations of herpes are among the most interesting and important of its characteristics, in the examples of neuralgic herpes, it is evident that the trunk of the nerve is involved, in other examples, as in herpes labialis, there is good reason to believe that only the peripheral fasciculi and cutaneous plexuses are concerned, and in other instances again, we have proof of the morbid state of the spinal nerve being transmitted to the nerves of the organic system, or *vice versa,* and notably in the case of the upper intercostal nerves to the cardiac nerves.

Experience would lead to the belief that, in comparison with other regions of the body, herpes zoster, or more exactly, herpes intercostalis, occurs with greater frequency than herpes attacking the regions supplied by the rest of the nerves, and although herpes zoster may be developed on either side of the body, yet it would seem to be more common on the left than on the right. Now, supposing this fact to be established, it would be worthy of consideration, how much of this predisposition might be due to communication between the affected nerves and the organic plexus of nerves which is distributed to the stomach and digestive organs, and the morbid influence resulting from such inter-communication. The exciting cause of herpes is generally cold, and cold would operate more injuriously upon nerves subjected to the frequent irritation of organs in a state of derangement, than it would upon nerves in a perfectly healthy condition. I make these remarks with a view to further investigation, but the fact is established, that predisposition, however occasioned, enters for a considerable part into the causation of the disease.

Amongst others of the *notabilia* of herpes, is the very great infrequency of its repetition. In general terms it may be said to occur very seldom more than once in a life time. That is to say, the form of herpes which is due to an affection of the trunks and larger branches of nerves; but, on the other hand, where the smaller branches of nerves are chiefly concerned and the nervous plexuses of the skin, a periodical occurrence of the eruption is one of the commonest pathological phenomena, as in the instance of herpes præputialis, or a recurrence in every instance of a common cold, as in herpes labialis. So, again, with regard to other general phenomena of herpes, although the eruption may never have been known to encircle completely the trunk of the body at one particular zone; cases are on record, wherein it has been seen on both sides of the body at the same time, but in different regions. Moreover, although it is usually observed in a single region only and affecting a single nerve, or two or three contiguous nerves; I have met with a case published in the *Journal of Cutaneous Medicine*, (vol. iv. page 158), in which it presented five separate tracks around the hemicycle of the trunk, between the collar bone and the groin. The case was that of a gentleman farmer, æt. 53, who had been the subject of attacks of eczema for twenty years. In the month of March, after some exposure to cold, he was seized with pain on the right side of the trunk with a burning, smarting, and tingling sensation in the skin. This was followed by the eruption of shingles, which encircled the side of the trunk in a series of tracks, ranging between one and three inches in breadth; of these tracks as seen on the dorsum of the trunk, one took the course of the supra-scapular muscle to the top of the shoulder, a second that of the infra-scapular muscle also to the top of the shoulder; the third passed below the scapula to the axilla; the fourth followed the line of the last ribs and lower border of the costal cartilages; and the fifth the curve of the crest of the ilium. In front of the trunk the two scapular tracks crossed the upper part of the pectoral muscle towards the sternum. The axillary track divided into two branches, one of which passed above, and the other below the nipple. The hypochondriac track continued forwards to the epigastrium, and the iliac track also divided into two branches, one of which crossed the flank below the level of the umbilicus, and the other followed the line of Poupart's ligament in the inguinal region; the five tracks of the dorsum of the trunk, being represented by seven on its anterior face.

If we turn to the phlyctenous affections before us in a therapeutical point of view, we shall discover our previous observations, with regard to the pathology of pemphigus and herpes to be fully confirmed, with pemphigus we find ourselves in face of a disease essentially constitutional in its origin and maintenance, and demanding as a first consideration constitutional treatment while in herpes, constitutional remedies are mere *adjuvantia*, and entirely secondary to local management.

Our constitutional review of the nature of pemphigus discovered that everything was unsound in the functions of assimilation, sanguification, and nutrition, and to the restoration of these great and important functions, our treatment must be addressed. We shall require good and nutritious food, wholesome air, proper attention to ablution, and tonic remedies. Bark, quinine, sulphuric acid, iron, and ammonia, will enter for a large share into our prescriptions. The digestive organs must be regulated by mild aperients, and only in cases where there is a special loss of nerve-tone and nutritive power in the skin, shall we need the crowning aid of arsenic.

In cases of herpes, where any functional derangement is present, and especially where functional disorder may be regarded in the light of a predisposing cause of the eruption, such disorder must be attacked, and if possible removed. I have remarked that herpes is sometimes associated, or to use an old fashioned phrase, sympathetic with visceral disturbance, as, for example, with bronchial and congestive disorder of the lungs, in which case, although bearing only indirectly on the herpes, there is ample scope for constitutional treatment. Again, in the neuralgia of herpes, with a view to allay the irritability of the nervous system, we may be under the necessity of having recourse to the bromide of potassium, to the hydrate of chloral, or to more decided sedatives, and in violent neuralgia to ten grain doses of sulphate of quinine.

The local treatment of both pemphigus and herpes, calls into exercise our routine measures for the management of vesicles and exuding surfaces. The dredging-box occupies a prominent place amongst our *armamenta*, then comes a desiccant powder, such as oxide of zinc, simple or diluted with starch, next a lotion of lime water with oxide of zinc, and in case of need, the oxide of zinc ointment rendered cooling and gently stimulating by the addition of an eighth part of spirits of wine. In the majority of cases, little more than these remedies will be required; they fulfil the intention of rest and protection so important in surgical affections, and when additional protection is demanded, we may obtain it by a simple dressing with dry lint, or an ointment of zinc or resin, maintained in position by strips of adhesive plaster, or by a bandage.

In cachectic cases of pemphigus, and in the ulcerative herpes of elderly persons, the local treatment may require the addition of local tonics, that is, of moderate stimulants, such as—a dusting with the powder of cinchona bark, the addition of carbolic acid to the ointments, or a lotion of chloride of zinc, the intention of these remedies being not only to give tone, but to counteract a tendency to decomposition and gangrene.

In the treatment of herpes zoster, a dusting with diluted oxide of zinc powder, or the lotion of lime water and oxide of zinc, covered with a layer of cotton wool, may be regarded as specific, and a similar zinc and lime water lotion applied to local blotches, or in situations where an external covering cannot be employed, is the best treatment that can be devised. On the lip, and in herpes præputialis, I have sometimes succeeded in arresting the cutaneous inflammation at its outset, by painting the spot with tincture of iodine, and, Lailler, as will be seen by the description of model No. 121, has had recourse to an alcoholic solution of perchloride of iron, consisting of one part to five.

In neuralgic herpes, our *armamentum chirurgicum* is sometimes set at defiance, fomentations of very hot water will occasionally confer a temporary relief, but the only remedy of real value is the subcutaneous injection of morphia, which I have several times practised with success. While in cases of frontal neuralgia, Mr. Bowman has obtained good results from the section of the frontal nerve.

A Course of Lectures

DELIVERED IN THE

CITY OF DUBLIN HOSPITAL,

BY ARCHIBALD HAMILTON JACOB, M.D. DUB. UNIV., F.R.C.S.I.

Ex-Ophthalmic Surgeon to the City of Dublin Hospital.

DISEASES AND INJURIES IN THE NEIGHBOURHOOD OF THE ORBIT.

INJURIES in the neighbourhood of the orbit differ in their characteristics in no essential respect from those occurring to other regions of the head, and I shall therefore leave your instruction in their treatment to my surgical colleagues, except as regards those cases in which the result may be influenced by the neighbourhood of the eyeball and tear mechanism.

The frontal bone and supra-orbital ridge, and the interposition of the frontal sinus, afford so perfect a protective shield to the anterior lobes of the brain that, although this portion of the cranium, being usually presented to attack, is necessarily more exposed to direct violence than any other part of the head, yet bad fractures or direct injuries of the brain are uncommon in this situation, except in those cases to which I shall presently allude in which the walls of the orbit are pierced. It is in fact much more to be feared in blows or falls on the forehead, that cerebral rupture or concussion or extravasation of blood has taken place from indirect violence, than that fracture has taken place. As, however, the whole strength of the orbital arch is antero-posterior, and depends principally on the upper and lower orbital ridges, the locality is vulnerable to blows indirectly transmitted from the back of the head, and thus fractures frequently extend through the orbital walls. Should such injury exist its diagnosis will probably be obscure, inasmuch as the symptoms of compression may not co-exist. An opening in the frontal sinus may be indicated by emphysema of the lid from escape of the air into the cellular tissue when the nose is blown. This condition gives rise to enormous distension, which might be mistaken for chemotic effusion; but if it appear from the colour of the swollen parts, the absence of tenderness to touch, or of symptoms of ophthalmic inflammation, that the swelling is caused by infiltration of air, a cautious diagnosis must be given. If the patient be desired to refrain from blowing the nose for a few days, the air will speedily disappear without necessity of any puncturation. Mackenzie points out that after a fall or blow on the head, should an extravasation of blood appear in the upper eyelid without its having received any contusion, it may be suspected that a counter-fracture of the upper wall of the orbit has taken place; if in the lower lid, that the floor of the orbit is broken.

Caries of the Orbital Ridges. Caries and necrosis of the bones are frequently caused by blows or falls upon the edge of the orbit, especially in syphilitic and strumous patients, and are attended with similar symptoms and results as present themselves when these affections arise spontaneously. The most usual form of orbital caries is in badly nourished scrofulous or syphilitic children, in whom it sometimes follows a trifling injury to the orbital ridge, but more commonly arises spontaneously. Disease of the bone may, of course, involve the wall within the orbit either primarily or as the secondary result of irritation from a foreign body, a circumscribed abscess, or a tumour, and may even prove fatal. Such cases will be spoken of when we come to the subject of orbital abscess. The cases of which I now speak involve the orbital ridge, and commence with what is supposed to be a boil, but ultimately becomes a sinus and pursues the usual course of resolution.

Treatment.—Such cases seldom produce dangerous symptoms, and are usually amenable to treatment. Phosphates of iron and soda, cod-liver oil, generous diet, and improved sanitation generally effect a speedy change for the better. It is of the first importance as soon as you suspect the bone disease or, indeed, at an early period in any case of abscess about the orbital ridge, to make a free and deep incision for the purpose of preventing the spontaneous bursting of the abscess and the consequent deforming cicatrisation. It may be necessary in any case in which a sinus is formed or a small sequestrum discovered, to eradicate the carious bone with the gouge; but this should not be done until the cachectic condition of constitution is set right by the treatment indicated above. In his explicit and valuable remarks on this subject, Mr. Haynes Walton quotes Mr. Bransby Cooper, who strongly recommended phosphoric acid, diluted with an equal weight of water, as being useful in facilitating the removal of sequestra, converting the phosphate of lime into a bi-phosphate, which is more soluble and more readily acted on by the pus. This lotion, Mr. Walton considers, is too strong to be used freely; but it may be applied accurately with a brush or a bit of lint. Mr. Bransby Cooper showed how an appreciable quantity of phosphate of lime taken from the pus of an abscess is an indication of the carious condition. If necrotic pus be placed under the microscope, an amorphous deposit will be seen, which will disappear on the addition of dilute acetic acid; or if the pus be burnt in a platinum spoon, the phosphate will be left as a greyish powder soluble in hydrochloric acid, and then precipitable with excess of ammonia. In default of early incision and proper treatment, the contraction of the orbital cicatrix, however, is liable to cause an extreme degree of eversion of the lid, a deformity which is hardly in the power of the surgeon to avert, and which will involve a subsequent operation. I exhibit (Fig. 1) an illustration, by Mr. Haynes Walton, of such a deformity, accompanied with dacryocystitis; but I shall leave the operation for the relief of such condition until I come to deal with ectropium.

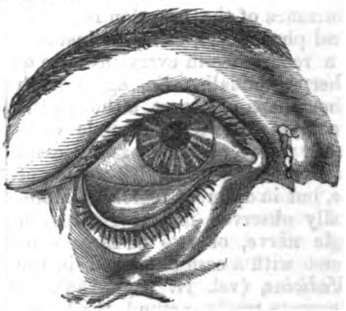

Fig. 1.

Orbital Ecchymosis. The superficial extravasation of blood under the skin, is an injury which scarcely requires or admits of any treatment. It results from a blow, and very frequently from the injudicious application of leeches to the eyelids, a locality for depletion which has no advantages, and the selection of which always superadds a black eye to the original deformity of the inflammation which it is sought to remove. If the opportunity can be seized immediately on the occurrence of the injury, the ecchymosis can be prevented extending by the application of cold water or ice. A bladder containing small lumps of ice is the best application; but, as it takes time to procure it, cold water dressings, with single scraps of old linen frequently changed, is the best substitute. The "raw beef-steak," which is the usual panacea, is a poultice, and, as such, an injurious application. The skin should on no account be punctured for the relief of swelling, lest the worse occurrence of suppuration or erysipelas should arise. A "black eye" defies the efforts of the surgeon, and goes from purple to black, from black to green, from green to yellow, and then returns to the natural appearance. The absorption of the effused blood generally occupies from ten days to a fortnight, according to the constitution of the patient, and can be hastened very little, if at all. Prize-fighters make use of poultices of scraped bryony root, which Mr. Tyrrell in his book says are to be made by mixing black bryony root, finely scraped, with crumb of bread, which is placed in a muslin bag over the contused lids for some hours. The root, however, is not to be obtained at druggists', and you will seldom have an opportunity of testing its efficacy, unless you can find it in the garden of a private patient. Lotions of arnica are also commonly used, but it is doubtful whether there be any virtue in them.

The following combination with muriate of ammonia is as useful as any other which can be prescribed:—

℞ Ammonia muriat., ʒiij.;
Tr., Arnic. mont., ʒvj.;
Aq. Laur. Ceras., ʒiij.;
Aq. Rosarum, ad ʒviij.

In cases in which injury is severe, and the skin inflammation very violent, leeches may be applied to the temple, but never to the ecchymosed spot, because they cannot re-

move coagulated blood, and only serve to increase the local lesion.

Injuries of the Eyelids. This form of injury is very common, and derives much importance from its probable effect in causing deformity of the lid and consequent displacement of the lachrymal mechanism. To illustrate the exact relations of the tear apparatus to the eye, I exhibit a drawing from Mr. Macnamara's hand-book of "Diseases of the Eye." From it you will be enabled to understand how slight a degree of malposition of the punctum or the lid is sufficient to give rise to distressing epiphora—a condition which I have often seen in old persons, in whom the punctum was everted barely the twelfth of an inch. It will, therefore, be remembered that, in the union of incisions in the lid, perfect apposition is necessary, and no rough, sticking-plaister surgery will be effective. If the wound only cuts through the skin, it is of no moment *unless it* remain neglected and unwashed, so that suppuration takes place. If, *however*, the lid and its cartilage be cut through, it must be properly united again, or it will acquire a permanent relaxation, which will give rise to a welling up of the tear within its margin, and a constant irritation to the conjunctiva. This is best done by the pin suture, as illustrated. (Fig. 3). The ordinary stitch is liable to cut out too soon, and does not maintain the apposition of the parts as accurately as is desired.

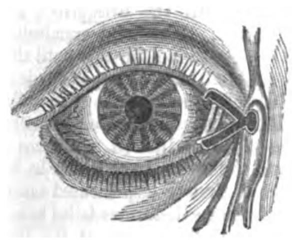

FIG. 2.

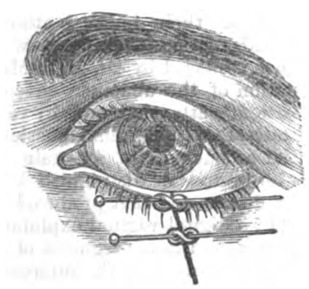

FIG. 3.

If the injury divide the canaliculus so as to sever the punctum from the lachrymal sac, an epiphora or permanent watering of the eye is difficult to avoid. It is, of course, necessary to unite the cut surfaces, but, without some further proceeding, it cannot be expected that the divided tear tube will unite in its natural situation. The usual book instruction is, that you should perform Bowman's operation of slitting up the canaliculus, having passed a narrow director, as figured in the margin, through the cut opening of the duct into the lachrymal sac, as will be described further on.

The introduction of such an instrument is, however, a difficult matter, in consequence of the excessively small size of the cut orifice of the tube and the difficulty of straightening it when it has no attachment on which you can put tension. I succeeded in a recent case in passing a fine silver wire or Anels probe through the punctum, and then through the tube into the lachrymal sac, and having brought the wound into apposition with this unerring guide, I put in my sutures. I then put a drop of sealing-wax on the wire close to the punctum to prevent it slipping within the canaliculus, and having cut off the remaining part of the wire, I fastened it in its position until the wound healed, and thus, with the aid of a little subsequent catheterisation of the tube, I maintained the patency of the tube uninjured. In any case, if you can succeed in so introducing the wire, there will be nothing lost, for you can subsequently split up the canaliculus with greater ease, if you find it impossible to maintain the duct as a free passage for the tears.

(*To be continued.*)

ABSTRACT OF A PAPER ON SPURIOUS, FEIGNED, AND CONCEALED PREGNANCY (*v*).

By Dr. Thomas More Madden, M.R.I.A.,

Examiner in Midwifery in the Queen's University in Ireland, and Assistant-Physician to the Rotunda Lying-in Hospital, Dublin, &c.

Spurious pregnancy, observes Dr. More Madden, is one of the most interesting subjects connected with obstetric medicine. The diagnosis between true pregnancy and pseudocyesis, including in this term cases of pretended as well as of spurious gestation, is oftentimes a matter of considerable difficulty and of the highest importance in a medico-legal, as well as in an obstetric, point of view. Hence, Dr. More Madden considered that the particulars of several cases of spurious, feigned, and concealed pregnancy, together with the observations suggested by them, might be of sufficient interest to warrant his calling the attention of the Dublin Obstetrical Society to them. The comparatively large number of cases of spurious pregnancy which have come under Dr. More Madden's observation within the last few years leads him to conclude that this morbid condition is of much more frequent occurrence than is generally supposed. Nor is it limited to any class of society as some writers seem to think, who speak of it as peculiarly affecting idle and over-fed, sterile, elderly, married women of the richer class. On the contrary, a large proportion of the cases now under consideration came before Dr. More Madden at the Dispensary for Diseases of Women attached to the Rotunda Lying-in Hospital, where, as might be expected, the patients are generally women of the poorest class. The period of life at which pseudocyesis most frequently occurs is a point on which the most eminent authorities differ. The late Sir James Simpson was of opinion that the disease occurs as often during the first year after marriage as at any later period. Dr. Churchill has recorded a case of this kind in a patient, aged seventeen. But Dr. More Madden's own observations leads him to agree with the late Dr. Montgomery, that spurious pregnancy is most frequently observed at the turn of life, when the catemenia, becoming irregular previous to their final cessation, are suppressed for a few periods. In pseudo-pregnancy most of the symptoms of pregnancy may be counterfeited with wonderful closeness; but the signs of pregnancy cannot be thus simulated. In such cases we may find morning sickness following suppression of the menses, enlargement of the breasts, appearance of an areola, a turgid state of the nipples and glandular follicles of the breast, occasionally the secretion of a lactescent fluid. Still more marked is the enlargement of the abdomen; indeed, much more so than would be the case at the corresponding period of true pregnancy. This abdominal enlargement he generally traced in such cases to dropsical effusion into the peritoneal cavity, or to the excessive deposit of fat in the omentum, or to dyspepsia causing the distension of the large intestines by fæces or flatus. In every case of pseudocyesis that came under Dr. More Madden's observation the patient asserted that she could distinctly feel the motions of the supposed child. The patient's nerves generally in these cases present the protean anomalous symptoms of pregnancy, such as longings, alteration in tastes, irritability of temper, neuralgic pains, &c., with great resemblance. As a rule, those who suffer from pseudocyesis have either born children previously and know all the symptoms of pregnancy by experience, or else have, as it were, "coached themselves up" on the subject, which occupies their thoughts most prominently, and apply their knowledge to themselves with such a morbid concentration on the one topic that they become mono-maniacs upon it, and deceive not only themselves but others.

No cases are more unsatisfactory to meet with in practice than these. The duty of a medical man is seldom

---

(*a*) Read before the Dublin Obstetrical Society.

more unpleasant than when he is obliged—in a case where a woman has for nine long months cherished the belief that she is with child, who has made all the usual preparations for her confinement, and who, perhaps, deceived by those anomalous periodic pains which sometimes occur in such cases, sends for medical assistance under the impression that labour is commencing—to inform her that her expectations are vain, and that she is not even pregnant. If, however, the physician should unfortunately fall in with the patient's opinion without sufficient examination into the case, and thus unconsciously make himself a party to her self-deception, he will, as soon as the real nature of the case becomes obvious, incur an almost incredible amount of odium from the patient, who not unnaturally, though often very unjustly, makes him the scapegoat for all the bitterness and vexation of which a woman's wounded pride is capable. Even when merely called in by another practitioner to see a case of this kind in consultation, the consultant is placed in a very awkward position. The patient is not pregnant, and the doctor must announce the fact; but still, as far as it is possible consistently with the patient's advantage, which, as in all other circumstances, is the first consideration of the physician, he should perform this duty so as to spare the reputation of his brother practitioner who may have pronounced her pregnant. In one case Dr. More Madden found this a matter of no small difficulty; but, even then, he succeeded in disabusing the patient's mind of the impression that she was pregnant, and still at the same time maintained her confidence in her medical attendant.

The causes of spurious pregnancy, besides those above mentioned, namely, "change of life," dyspepsia, dropsy, and obesity, are very numerous. Two of the most interesting of these are molar-pregnancy and uterine hydatidiform disease. Molar-pregnancy is a comparatively rare form of spurious pregnancy, although the poorer class of dispensary patients frequently date commencement of uterine diseases from the time at which they had what they term a false conception. Generally, however, on inquiring into such histories we find the case to have been one of an ordinary miscarriage; and in two cases in which the so-called mole was kept for examination, Dr. More Madden could discover nothing but a simple clot. A few cases of molar-pregnancy have, however, come under observation. There is no possibility of distinguishing between these cases and those of true pregnancy in the early period of supposed gestation. These substances are generally expelled from the uterus between the third and fourth months; but if retained beyond the fifth month, the absence of the positive signs of pregnancy will, of course, decide the question.

Pregnancy may also be simulated by uterine hydatidiform disease; and four cases of this kind have come under Dr. More Madden's observation. In all these cases the patients supposed themselves with child until they were undeceived by the expulsion of the hydatidiform mass from the uterus. In one case, the patient, a multipera, insisted that she distinctly felt the child's motions. The generally-adopted modern opinion is that these hydatidiform moles are the result of the pathological degeneration, or abnormal development of some of the embryonic structures already existing in the uterus. But uterine hydatids sometimes occur under circumstances where this theory could not possibly apply,—that is, in cases in which pregnancy has never existed. Dr. More Madden is of opinion that we must look for the explanation of such cases to those constitutional changes which lead to the formation of true hydatids in other parts of the body, or else to morbid action set up within the ovary of an unimpregnated female, and which results in the production of hydatidiform disease in a Graafian vesicle, and of its escape from the ovary into the uterine cavity, where it continues to increase in bulk until it excites uterine irritation and expulsive action. Pregnancy may furthermore be counterfeited by ovarian disease, ascites, fibroid tumours of the uterus, physometra, hysteria, and some other morbid conditions, on the nature and diagnosis of which the writer enlarges.

The diagnosis between true and spurious pregnancy must be founded, continues Dr. More Madden, on a careful analytical examination of the symptoms of each case, testing them by a comparison with the unequivocal and recognised signs of pregnancy. Physicial examination affords comparatively little assistance in this until after the fifth month, and as a rule neither patient or physician ever suppose the possibility of pseudocyesis at an earlier period. Dr. More Madden professes himself somewhat doubtful as to the value of auscultation as a means of diagnosis in such cases, and refers to cases which he has previously published as proof that if experienced auscultators have, as he asserts, in those instances failed to hear the fœtal heart or placental rouffle even at the ninth month in cases where a living child was born a few days after the examination, how much more uncertain must this test be at a much earlier period of pregnancy and in the hands of less experienced auscultators. In proof of this the writer refers to two cases of pseudocyesis in which the patients were pronounced pregnant on the faith of their medical attendants imagining that the sounds of the fœtal heart were audible. More dependance is placed by Dr. More Madden on a manual examination of the abdomen so conducted as to take off the patient's attention, and by relaxing the tense and rigid state of the abdominal muscles usual in such cases, enable the accoucheur to ascertain the exact condition of the uterus, and to distinguish between enlargement caused by disease and that produced by pregnancy. To assist in this, a digital vaginal exploration of the state of the os, cervix, and lower segment of the uterus is also necessary, and the nature of the information thus afforded is particularly pointed out. A large number of cases illustrating the foregoing observations are detailed. In the first of these Dr. More Madden was summoned in great haste to see a lady residing some distance from Dublin, who was supposed to be in labour. On his arrival he found the patient, a primipara, lying in bed in the usual obstetric position on her left side, pulling hard at a strap fastened to the foot of the bed, and groaning loudly with the pains, which appeared very strong and in rapid succession. Her husband and friends were in a state of great anxiety, as the nurse said she had been a long time in the second stage. On making an examination, which was effected with some difficulty owing to the resistance of the patient, the cervix was found very long and narrow, the os small and circular, and the uterus very small. The abdomen was extremely large and tympanitic. As she was in an extremely nervous, excited condition, she was merely told that she was not in labour; a warm aperient draught was ordered, and the propriety of consulting another accoucheur was suggested in a few days. She soon afterwards came into town to see Dr. More Madden, and on its being hinted to her that she was not pregnant, she became very indignant, pointed triumphantly to the lactescent fluid which she squeezed from her breasts, and insisted that she could feel the child's movements very distinctly. The next case related is also one where pregnancy was simulated by flatulent distension of the large intestines, and in which a well-marked areola was observed. This patient came under treatment at the dispensary, and was rapidly cured of all her symptoms by a combination of tonics and warm purgatives. The third case occurred in private practice, the patient being a lady residing in the country, whom Dr. More Madden saw in consultation under the following circumstances: She was a married woman, aged forty-one, of stout, plethoric habit, having no family, although over ten years married. Her menses until within the last year had always been regular, and her general health excellent. Eleven months previously she commenced for the first time to suffer from nausea and retching every morning. Shortly after her breasts began to enlarge and became painful, her appetite was capricious, her nervous system evinced considerable derangement. Diarrhœa now commenced, and persisted until the time of the consultation. Her menses still continued, but instead of lasting for three or four days as usual, now only remained for a few hours at a time, and were extremely pale and scanty. She consulted her medical attendant, who said that she was probably pregnant, but advised her to consult an accoucheur in Dublin. This, however, she refused to do. The date fixed on for her expected confinement was the end of April. Four months from the commencement of these symptoms she asserted that she began to feel the motions of the child, which gradually became stronger, and the abdomen continued to increase in size. Shortly after the time, the docter imagined that he was able to detect the fœtal heart and placental souffle. The time of her expected confinement at last arrived; the nurse took up her quarters in the house, some of her family came down from town to be present at the anxiously-looked-for event, for which all the usual preparations were now completed. No sign of labour, however, manifested itself, as week after week passed beyond the expected time. Her friends got tired out, her family returned home, and she herself became exceedingly nervous and desponding, as her mother had died of dropsy at about her present age. But still she insisted as strongly as ever that she could feel the child's motions distinctly. Such was the history of her case up to the time Dr. More Madden was asked to see her. On examination, the breasts were found slightly enlarged, but soft and flaccid. The nipples were somewhat turgid, there was a well-marked areola, and the glandular follicles around the base of each were prominent. The abdomen was about as large as that of a woman at the end of the ninth month of pregnancy; but the uterus was small, as was discovered with some difficulty when the resistance offered by the tense and arched abdominal muscles was overcome. The abdomen was resonant on percussion, the large intestines being enormously distended by flatulency, the movements of which, as is usual in such cases, she had taken for those of the child. There was also a considerable amount of fluid in the peritoneal cavity. The vagina was pale, the cervix and os uteri were low down, hypertrophied, and extensively ulcerated. Her chagrin when informed that her preparations were not necessary for the present at least was naturally very great. Her medical attendant now coincided in recommending change of air, sea-bathing, and a combination of tonics and diuretics. Under this course the abdominal swelling and other symptoms of pseudocyesis gradually disappeared. The ulceration was treated with equal success, and her condition soon became more satisfactory than it had been for a long time previously. The next case was that of a clerk's wife, aged twenty-four, who had had two children, and now applied for advice, believing herself to be five months pregnant, as she suffered from all the symptoms of pregnancy which she had formerly experienced, with the exception that her menses still continued. On examination, a large interuterine fibroid tumour was discovered. The fifth case was that of a woman, aged twenty-nine, who had been three years married, and had given birth to two stillborn children. She first applied for advice in July, believing herself then pregnant, and did not return till the following February, when she came for a ticket to admit her into the hospital. She had a menstrual discharge every month, but with this exception—she had all the symptoms she was familiar with during her former pregnancies. Her abdomen had enlarged; she imagined that she could feel the fœtal motions; the breasts were developed; there was a deep areola around the nipples, which were turgid; the glandular follicles at their bases were prominent; a lactescent fluid was secreted; she, morever, suffered now from frequent micturition, tenesmus, and irregular pains in the back and abdomen, leading her to think that labour was approaching. On examination, the abdomen was found very tense and so protruded as to be fully equal in size to the ordinary bulk at the end of the ninth month of pregnancy. The shape of the abdominal tumour, however, was very different, the umbilicus being retracted, and the tumour, which was globular and uniform, disappearing to some extent when her attention was taken off, so that Dr. More Madden was able to satisfy himself that there was no uterine enlargement whatever. The vagina was pale, and the os and cervix that of an unimpregnated uterus. The patient was exceedingly dissatisfied when informed that she was not pregnant, and expressed her opinion on the subject in very indignant terms. Still she returned in a few days, and was treated by aperients and tonics, under the use of which she rapidly regained her accustomed health.

◆

CASE OF INTESTINAL OBSTRUCTION.—DEATH IN FOURTEEN HOURS.

By Christopher Elliott, M.B., L.R.C.S.I., &c.

On Feb. 10th, about half-past ten a.m., I was sent for to see Margaret S——, a nurse in the Fever Hospital, who had been taken ill suddenly about one a.m., whilst on night duty, with a violent pain in the abdomen and incessant vomiting.

On my arrival I found her in a state of complete collapse, the features shrunk and pinched, the pupils greatly contracted, the pulse very feeble, and the extremities cold. The vomiting, which had hitherto been incessant, had somewhat abated, but she complained of an intense pain of a colicky character in the abdomen, about the umbilical region. There was no tenderness on pressure. On the closest investigation no hernia could be detected. Early that night she had taken a dose of castor oil, and had passed something dark like blood, but I did not see this, ~~as~~ it had unfortunately been thrown away. She was ordered whiskey, hot jars to feet, poultice to abdomen, and morphia (gr. $\frac{1}{8}$ instanter, to be repeated in an hour, and every second hour after that if necessary). The first dose of morphia remained on her stomach, but soon after taking the second vomiting recommenced, and continued without intermission till she died about three p.m. All the information I could obtain respecting the previous history of the case was that during the week she had complained of loss of appetite, and, to use her own words, she felt as if something had gone astray in her inside.

On making the post-mortem about four feet of small intestines were found strangulated by a small band of lymph about as thick as a stout ligature, which passed from one part of the mesentery to another, completely occluding the intestinal canal. The strangulated portion of the intestine was of a dark claret colour, and when opened was found to contain dark coagulated blood.

Transactions of Societies.

THE DUBLIN OBSTETRICAL SOCIETY.

The Society met on Saturday evening, 17th February, at the Royal College of Physicians.

Dr. Kidd, President, in the Chair.

Dr. T. More Madden read a paper on

SPURIOUS, FEIGNED, AND CONCEALED PREGNANCY,

which will be found at page 225.

After a few remarks by the President and Dr. Atthill, Dr. McClintock read the following paper :—

THE USE OF A HEMP SAW FOR THE EXCISION OF POLYPI.

He said he had had but a very limited experience of this method of excising vaginal and uterine tumours, but he thought it would prove very simple and useful, and in many cases more feasible than other modes of operation. His attention was first directed to the matter by the paper read by the President on the subject of decapitation in utero, by sawing the neck through with a hempen cord. It occurred to him that the same method might be applied for the extirpation of uterine polypi; and he determined to use it on the first opportunity that presented itself. Recently, Dr. Symes, of Kingstown, sent to him a married lady who had borne four children, and who was suffering from repeated hæmorrhages from the vagina. A large polypus was discovered in the vagina, and on the 10th of last month he met Dr. Symes for the purpose of extirpating it. The polypus was the size of a turkey's egg, the neck of it being about as thick as a man's thumb. Dr. McClintock then described the operation. The polypus having been drawn down to the vulva, a loop of fishing-line, introduced through Gooch's double canula, was cast round the neck of it, and in thirty-five seconds by the sawing process, it cut through the neck of the growth which was then removed by the vulsellum. The tumour weighed two and a-half ounces, and the section of the pedicle was one inch in diameter. It was a true polypus, presenting a well-marked capsule. The operation was facile, expeditious and unattended with pain or bleeding. No doubt the polypus was of a kind that admitted of removal by means of the scissors or écraseur, so that it presented no unusual difficulties. The ligature was applied and used through Gooch's double canula to protect the vagina from injury by friction of the ligature. He had seen the wire-rope break in attempting to remove fibrous tumours, thus causing great inconvenience. The hemp ligature might also give way but they could guard against that occurrence by employing a long piece of cord, and from time to time bringing a fresh portion to act upon the surface they were operating on. Dr McClintock then mentioned the results of several experiments which he had made to test the efficacy of the cord. In ten minutes I cut through the tendon in the hock of an ox which he did not think the écraseur could be capable of doing. He admitted that it was possible that this method of operation might be followed by hæmorrhage or pyæmia, but this was a matter which experience alone could determine.

The **PRESIDENT** said as Dr. McClintock had alluded to the use of a hemp saw for decapitation, he took that opportunity of exhibiting to the Society the result of the use of that saw. He had before him the body of a child that he delivered on last Tuesday week, in the manner which he suggested in his paper read last Session. He had not then fully tried the method of passing the cord that he ventured to suggest, but he tried it in this instance, and it answered his expectations very fully. This was a case of transverse presentation. When he saw her, the woman had been many hours in labour; the right arm was hanging out of the vulva, and the left lying in the vagina. The patient was under the care of Dr. Arthur Ringland, who sent for him. When he arrived Dr. Ringland passed his hand into the uterus and tried to turn the child, but the uterus was so firmly moulded round it, that without using more violence than was prudent, he could not seize the feet. Finding that the child was dead he determined to decapitate. He passed a cord round the neck by means of a catheter—a silken cord, the very same he had used on a previous occasion, and proceeded to divide the head from the neck. In a minute and a half section was made. One observer said he was rather over a minute, and another that he was a minute and a half in performing the operation. The total operation lasted twenty minutes.

DR. BEATTY said that any one who had gone through the toil and difficulty of the old operation of evisceration in a case of transverse presentation when the arm was down in the vagina, the child a large one, and no possibility of turning, would rejoice at the introduction of such an operation as the President had brought before the Society, and which had been employed and further utilised by Dr. McClintock. The simplicity of Dr. Kidd's operation seemed to him almost miraculous, contrasted with that he alluded to, and it was one of the greatest boons conferred in midwifery in modern times. Its application to cases of tumours was a matter of considerable importance. Dr. McClintock had alluded to the possible occurrence of hæmorrhage, which had struck him also. The rapidity of the cutting through might leave the possibility of hæmorrhage, which was avoided by the slower process of the écraseur, the crushing effects of which were calculated to prevent bleeding.

DR. RINGLAND believed the occurrence of hæmorrhage was by no means an impossible event in the progress of this operation. Dr. McClintock recalled to his memory a case which occurred under the President's notice, and his (Dr. Ringland's) within a few weeks past, where an enormous tumour presented itself, and where, by the ordinary process of the écraseur it became impossible to remove even portions of it. Every time the écraseur was tightened, it slipped off the tumour. The operation was postponed till the following day in consequence of the neck of the uterus not being sufficiently dilated by sea-tangle; and whether it was the handling the patient was subjected to or not he could not say, but she quickly sank. That case directed attention to the possibility of adopting some means whereby an enormous tumour, such as existed in that instance, might have either the wire of an écraseur or some other means applied to it, and they came to the conclusion that in the event of a similar case, an instrument somewhat analogous to the instrument of Pajot, might be employed for the passing of the means whereby the cutting process was to be effected—whether by wire or a hempen ligature—an instrument such as that used for plugging the nares. He regretted that he did not see the entire of the operation performed by Dr. Kidd. He did not see the way in which the ligature was applied, having been present during the cutting operation only, and he believed that it was done in little more than a minute.

DR. CRONYN could not accept the idea that decapitation, involving as it does the risk of leaving the fœtal head in the uterus, was a good or safe operation. He had frequently seen the operation of evisceration performed, and it was invariably a safe and easy operation, and all of the patients made easy and quick recoveries. They must consider the difficulty in which Dr. Kidd, or any other practitioner would be placed, if the os uteri contracted on the head too quickly to allow the forceps to be applied, and the practitioner had to retreat, leaving the head in the uterus. As to the use of the hemp saw in removing polypi, he had no doubt it was useful, but at the same time he had seen polypi taken away by Gooch's canulæ and a tight ligature, and all had gone on well.

DR. ATTHILL said that every one who had experienced the difficulty of encircling with a wire an intra-uterine tumour, would be grateful to those who lessened the difficulty of dealing with such cases. He had himself suggested a modification of Gooch's canulæ, but he did not think he would use it again. It did very well if a hemp ligature were sufficient, but that was seldom the case, and the difficulty of passing wire around the tumour with the canulæ was enormous. He saw Dr. Denham succeed with his (Dr. Atthill's) instrument in a case of extra-uterine polypus, but the attempt to pass a wire round an intra-uterine polypi with the canulæ was a matter of serious difficulty. Dr. McClintock's method was ingenious. He had the good fortune to be present at a trial of it, and although the operation was not altogether successful, it gave him a good idea of it. It was a case of intra-uterine polypus low down in the uterus. The ligature was passed round the tumour certainly, but after a very few seconds of sawing the ligature gave way. That was the real difficulty to contend with. There was great friction of the cord, and until some means of lessening this were devised, the liability to its breaking would be very great. It would be a matter of difficulty to cut through a thick pedicle without the cord giving way, unless the canulæ were modified in such a way as to cause the two ends to diverge somewhat, thus lessening the amount of friction. He was not himself afraid of hæmorrhage, and as to pyæmia, he did not think there was any additional risk of its following the use of the hemp saw. He disagreed with Dr. Cronyn as to the dangers likely to follow the attempt to remove polypi by the old and now discarded method introduced by Dr. Gooch. He had never lost a patient by practising it, but more than one had been at death's door; and they knew from the statistics of the practices more extended than his, that the mortality after the application of the ligature in the old method, and the tightening it day by day was great indeed. He entirely coincided with Dr. Beatty as to the advantage of decapitation, which he thought would make a complete revolution in the practice in case of arm presentations. His knowledge of eviscerations was very unfavourable. It was a most tedious, horribly disgusting operation. On one occasion he was two hours before he could get his hook so fixed as to get down the body. He should run the risk of having the head retained in utero, which was only possible, rather than encounter the difficulty and trouble of evisceration, which was certain. If the os contracted somewhat, they could, by the use of Barnes' dilator, open it, so as to perforate the head in utero, or seize it with the forceps.

After some remarks from Dr. Frank Thorpe Porter,—

Dr. Thomas More Madden referred to the subject of decapitation by means of the ligature as a substitute for embryotomy, as proposed in certain cases as a last resource by Dr. Kidd. Whilst he (Dr. Madden) agreed, under certain circumstances, with the suggested operation, he could not admit that all the practitioners into whose hands this new and facile method of decapitating a fœtus in utero might come, would be as patient, as skilful, or as conscientious as Dr. Kidd; therefore, he could not join in the delight with which some previous speakers had welcomed the new operation. He thought that embryotomy was an operation so awful, and so horrible, that nothing should be done to familiarise its use, or to substitute for it another operation more facile, less wearisome to the operator, and less revolting to the spectator. He therefore thought that it was impossible to use too great a degree of caution before arriving at the conclusion that the child would not be born alive, and that it was by no means desirable that embryotomic instruments should be improved, and rendered more easy to use. On the contrary, he thought too much attention could not be given to the improvement of the means for deliveries of living children from living mothers, with safety to both, by the forceps, or by other means.

Dr. Denham believed the operation to be by no means so free from dangers as some appeared to suppose, but he could well conceive a case in which it might be attended with ten-fold the difficulty that Dr. Kidd encountered. In many of these cross-births the child was unusually large. If they took a case of first labour, a large child, the parts not well dilated, the waters not drained for hours, he could conceive a great amount of difficulty in removing the head of a premature birth. Nay, more, in endeavouring to pull down the body of a decomposed child, he had seen the os close on the neck, and the head left behind, and he had experienced very great difficulty in the removal of such a head. He could not coincide in the remarks of Dr. Madden. If a cross-birth took place, and the practitioner came to the deliberate conclusion that he must deliver the woman, the quickest and the easiest method of doing so was what he was bound to adopt. The safety of their patients was the first matter to be considered by obstetric practitioners. Their own toil, disgusting though it might be, was of small importance compared with the life of their patients. He regretted that they had heard nothing more practical as to Dr. McClintock's paper. He had seen it tried without success on a large uterine polypus. There was a great distinction to be drawn between the cutting off of the head or thigh of a child, and the removal of a polypus in the uterus, and Dr. Kidd's plan, while adopted for the former, might not prove so efficient in the latter operation.

Dr. McClintock, in replying, said he must first express is admiration of the operation which the President had inroduced to their notice. It was not a well-founded objecion against the operation to say that it was easy and safe, rovided it was capable of effectually fulfilling the intention ith which it was undertaken. There was some grounds to pprehend there might be difficulty in extracting the head ter the removal of the body. Any one reading "Smellie's idwifery," must have his mind filled with apprehensions that point; it seemed to have been to Smellie a regular gbear. When the removal of the head was undertaken ithout delay. there would seldom be any difficulty in doing ; but he did not think the difficulty, whatever it might , was to be put in comparison with the danger and trouble evisceration. If there were any merit in the method of moving vaginal uterine tumours which he had brought fore them that evening, it had grown out of Dr. Kidd's per, the reading of which put the idea into his (Dr. cClintock's) mind. There were two points which he nted to establish, and he thought he had succeeded in ing so. One was that a ligature of this kind—a "hempw"—was capable of cutting through any structure they re likely to meet with in uterine tumours. The other point he endeavoured to prove was that with this contrivance of Gooch's canulæ, they could with more facility carry a ligature round the neck of a polypus when it was very high up, or very large, than if they used a wire ligature. In one case alluded to the canulæ broke, and hence the importance of using a very strong canulæ. The failure of the operation was owing to the imperfection of the instruments. In the other case (that alluded to by Dr. Denham), the ligature was successfully carried round the neck of an intra-uterine tumour, but the edges of the orifices of the canulæ were so sharp that they cut the ligature across in a moment; therefore, in the construction of the instrument for this operation, the eyes should be rounded off so that they should not fray the cord.

The President remarked that if the practitioner had a cephalotrobe beside him, he need not fear the risk of the head remaining in the uterus.

The Society then adjourned.

MEDICAL AND CHIRURGICAL SOCIETY.

Annual Meeting, March 1st.

T. B. Curling, F.R.S., President, in the Chair.

The report having been adopted, the President addressed the meeting. He congratulated the Society on their having accepted the management of the Marshall Hall Memorial Fund, which he confidently hoped would give great encouragement to the prosecution of researches on the physiology and pathology of the nervous system. He likewise trusted that the enlargement of the premises, and the great increase in the space for library accommodation, would meet the wishes and convenience of the Fellows. In commencing the usual annual obituary of deceased Fellows, the President regretted that the roll this year was larger than it had been for many preceding years. It included the names of Dr. Tanner, Dr. Hennen, Dr. Hyde Salter, Mr. Samuel Solly, Mr. Langston Parker, Mr. Robert Wade, Dr. George Blackman (United States), Dr. George Edward Day, Mr. Thomas Hammerton, Dr. James Abercrombie, Dr. John G. Goulstone, Dr. Wm. England, Mr. Simon Murchison, Mr. Herbert Chalmers Miles, Mr. John W. Hubbard, Dr. George Scratchley, Mr. Charles Revan Alexander, Dr. G. F. Dorsett Evans, Dr. Patrick Miller, Mr. Henry Derviche Jones, and Mr. Charles Beevan. The President also referred to the deaths of two distinguished Honorary Fellows of the Society, Sir John F. W. Herschell, and Sir Roderick Impey Murchison, and gave sketches of the lives and researches of these several deceased gentlemen.

The President announced the result of the ballot for officers and Council for 1872-73, as follows:—President: Mr. T. B. Curling, F.R.S. Vice-Presidents: Dr. A. P. Stewart, Dr. Barclay, Mr. Critchett, and Mr. J. A. Kingdon. Treasurers: Dr. Balfour, F.R.S., and Mr. Birkett. Secretaries: Dr. E. S. Thompson and Mr. Thomas Smith. Librarians: Dr. T. K. Chambers and Mr. Charles Brooke, F.R.S. Other members of Council: Dr. E. Ballard, Dr. Greenhalgh, Dr. George Harley, F.R.S., Dr. H. J. Sanderson, Dr. Walshe, Mr. W. O. Chalk, Mr. Gascoyen, Mr. Hulke, F.R.S., Mr. Edwin Saunders, and Mr. Savory, F.R.S.

The meeting then adjourned.

Militia Surgeons.—In the House of Commons on Friday night, Mr. Cardwell stated that the services of militia surgeons would not be required when the new system was introduced for attendance on the staff and inspection of recruits, but they would be required during the annual training.

Apothecaries' Hall of London.—At a Court of Examiners held on the 7th inst., the following gentlemen, having passed the necessary examinations, received the L.S.A. diploma, viz.:—Messrs. Andrew Duncan, of Henrietta-street, Covent-Garden; Edward James Nix, of West Ham; and George Richard Shemilt, of Tean, Staffordshire. The following passed the primary professional examination, viz.:—Messrs. Henry Beale Collins, of King's College; Joseph Foreman and James W. H. Hawton, of Guy's Hospital; and Henry Cecil Moore and Richard Smith, of the Birmingham School of Medicine.

SPECIAL REPORT ON FOODS,

INCLUDING DIFFERENT KINDS OF

FARINACEOUS PREPARATIONS FOR INFANTS AND INVALIDS,

MEAT EXTRACTS, AUSTRALIAN MEATS, &c.,

Together with reliable Chemical Analyses by Competent Professors.

[PREPARED EXPRESSLY FOR THE "MEDICAL PRESS AND CIRCULAR."]

(*Continued.*)

REPORT ON THE FARINACEOUS FOODS NOW BEING ADVERTISED AND LARGELY USED FOR DIETETIC PURPOSES.

IN considering these important and very generally used articles of commerce, some few points of difficulty present themselves.

A glance at the numerous advertisements which teem in the newspapers, and a moment's consideration of how many thousands of pounds are expended in these advertisements, show that there is a very large margin of profit to induce such a concentration of commercial enterprise in this direction. If, therefore, a consumer takes his starch in a prepared form, with a grandiloquent name, and at an advanced price, instead of consuming his starch in the form of rice, or the potato, he is at least entitled to a reliable guarantee that nothing unwholesome has been used in its manufacture, and that the alimentary nature of the material has been improved as regards its digestibility. It is with this view that, as far as possible, the prices of these preparations, as sold in the shops, are placed in this report in juxtaposition with the real quantity contained in each packet. No opinion is offered as regards their actual value, but this part must be considered strictly in connection with the analyses given. There are a few that bear relatively to their merits a most exorbitant price.

In the more recently introduced foods a marked improvement will be observed. They are generally some definite alimentary substances, carefully prepared, with a view to dietetic value; not a heterogeneous mixture put together and merely concocted so as to represent five-tenths profit to the proprietor, two and a half tenths to the advertising mediums, and the remainder—well, the said remainder may as well be left to the oblivion it deserves. Hid under the mask of this grandiloquent name, it is probably something that the consumer would not feed his horse upon. Thanks to the chemist and the microscopist, the caterer for public suffrage knows that he must run the gauntlet of science; and this great social question of the day—dietary—is slowly but surely becoming one of the important legislative questions. The criminality of food adulteration is universally accepted—legislatively it cannot be far distant.

The three important points to consider in connection with the history of farinaceous foods are the starch, gluten and the other nitrogenous substances, and, lastly, the mechanical preparation of the seeds. Starch, which is the chief ingredient in such substances, is classed as one of the heat-forming foods. The principal heat-formers are starch, fat, sugar, and gum. Nothing can be more fallacious than the mode in which this is generally stated in the popular books on dietary. Now, food is arbitrarily divided in such works into "fuel" (starch, sugar, &c.) and nutritious or flesh-forming food. Thus nothing can be more obsolete or contrary to physiological research than to imagine that such food is simply consumed for the maintenance of animal heat. All injesta undergoes a process of oxidation by which heat is generated, the nitrogenous equally with the non-nitrogenous, such as starch; and out of this general resolution of molecules the different bodies—essential either for a reconstruction of the edifice, or to supply energy—are elaborated. The so-called animal heat is a corrollary from multifarious chemical actions taking place in the human body. To speak of the "fuel" of a man's injesta, or to convey that eighty per cent. of his solid food is merely supplied to maintain the animal heat, evidently tends to give an erroneous impression.

The gluten, or nitrogenous portions of some cereals, constitutes 10 to 14 per cent., and we may consider, in connection with that substance, the vegetable albumen and other nitrogenous bodies, which occur in small proportions. Although of great value from a dietetic point of view, these farinaceous foods can only be considered as amylaceous foods, and are from that reason almost invariably given with milk.

As they are largely used for children and invalids the mechanical dressing of the cereals is of great importance when considered in connection with digestibility, &c.

We would here point out that which, upon physiological grounds, is a grave error, viz.—the employment of starch foods as the staple diet of infants. For children beyond a certain age, for adults, and as delicacies for the table and for invalids, these foods have very strong claims for general adoption; and for the before-mentioned purposes we would desire to see them even more extensively used than they are at present. But to stuff infants with foods they are absolutely unable to digest, injures both them and the reputation of the article mal-administered.

The value of amylaceous or starchy matter can be best appreciated by a reference to the daily diet of an adult in health. Meleschott gives as a normal daily diet—

Protein substances . .	130	grammes
Fat	84	„
Starch	404	„
Salt	30	„
Water	2,800	„

At the conclusion of this report the actual composition of the grains, &c., from which these foods are elaborated, will be given in a tabulated form; but *ad interim* we will proceed to the consideration of the samples.

COLMAN'S BRITISH CORN-FLOUR.

Prepared at Cannon street, London.

The advertisement states that "it is prepared from RICE (the staple food of more than Three Hundred Millions—300,000,000 of People), and is unequalled for Blanc-mange, Custards, Puddings, Cakes, Soups, &c., and is the most wholesome and easily-digestible Food for children and invalids."

Testimonials are given from Edwin Lankester, M.D., F.R.S., Arthur Hill Hassall, and many others.

"The Medical faculty, connoisseurs, and professed cooks declare Colman's British Corn-flour is superior to all other preparations."

A large number of receipts are printed upon the wrapper, in all of which milk enters largely into the composition.

This preparation, when examined by the microscope, was found to consist entirely of rice starch. It was very free from odour, and only gave ·4 of a per cent. of ash, fairly abounding in phosphates. It therefore had been carefully prepared, and may be viewed as a pure article.

In considering rice starch as a diet it may be viewed as one of the purest and most definite forms of starch. Even the grain itself, as will be seen from analyses by Polson of the cereals, is very free from fat and nitrogenous substances :—

Analysis of Patna Rice, by Polson, J. Pharm.

Water	9·8
Starch	78·8
Nitrogenous substance	7·2
Fat	·2
Cellulose	2.0
Gum and sugar	1·1
Ash	·9
	100

Composition of the Ash of Rice, by Zedeler.

Potash	20·2
Soda	2·5
Lime	7·2
Magnesia	4·25
Silica	1·4
Phosphoric anhydride	60·2

From the chemical purity of rice starch is perhaps due the binding, or want of laxative quality, of this grain. In speaking of the potato, compared with rice, Johnson gives the following interesting remark. The potato is grown over a greater range of latitude than any other cultivated plant. "The dried potato is less nutritive, weight for weight, in the sense of supporting the strength and enabling a man to undergo fatigue, than any other extensively used vegetable food of which the composition is known, with the exception only of rice and of the plantain. It approaches nearest, indeed, to rice, though it is somewhat superior to that grain. Thus the dry substance of these three forms of food consist of—

	Rice.	Potato (dry).	Plantain.
Gluten	7½	8	5½
Starch	92½	92	94¾
	100	100	100

"There is, therefore, a remarkable similarity among these three kinds of food, in so far as they all differ from our cereals and other grains and roots in containing a smaller proportion of the ingredients represented by the gluten of wheat.

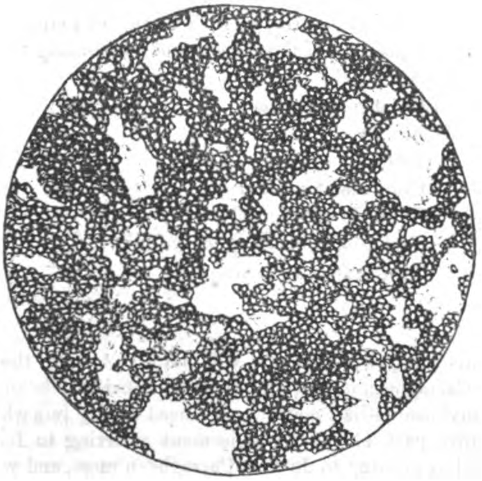
"And in the use of them all it is remarkable that a chemical or physiological likeness is indicated by the observation that the tribes of people who live exclusively, or even chiefly, on any of these three vegetable productions, are distinguished by the size and prominence of their stomachs. The Hindoo, who lives on rice, the negro, who lives on the plantain, and the Irishman, who lives exclusively on the potato, are all described as being more or less pot-bellied. This peculiarity is to be ascribed in part, I suppose, to the necessity of eating a large bulk of food in order to be able to extract from it a sufficient amount of necessary sustenance."

It must be borne in mind that Johnson here speaks of those who live upon this food to the exclusion of animal diet.

"And this deformity is somewhat less conspicuous in the potato-eater than in the plantain-loving negro, or even the rice-devouring Chinaman and Hindoo ; and is probably to be ascribed to the somewhat larger proportion of the gluten ingredient which is present in the potato."

The granules of rice starch, although extremely small, are so characteristic that they could not be mistaken for any other.

FIG. 1.



The preparation under examination makes a very firm *blanc-mange*, or jelly of considerable solidity.

"Colman's Corn-flour," therefore, may be considered a pure preparation. It is sold in pound packets, retailed at eightpence.

SEA-MOSS FARINE.—"A New Food."

"This packet will yield sixteen quarts of Blanc-mange."

The packet specified contained about four ounces, and is retailed at one shilling.

The following appears in the advertisements :—

"In the frigid regions of Iceland the Sea Moss has long been extensively used, as an article of food, which, in the eyes of the Icelanders, has no rival. This people said of it—'It is the gift of a bountiful Providence, which sends us bread out of the very stones.'

"It is most excellent as a porridge for the sick. As a nutritious soup, nothing can surpass it.

"In Saxony, Moss has been extensively used in the making of bread. According to an estimate published by the government of that country, 'six pounds eleven ounces boiled with fourteen times its quantity of water, and baked in this state with thirty-nine and one-half pounds of flour, produced one hundred and eleven and one-half pounds of excellent household bread. Without this addition, the flour would not have produced more than seventy-eight and three-quarters of bread ; therefore, this addition of six pounds eleven ounces of Moss occasions an increase of about thirty-two pounds of bread.'

"A writer in the 'American Encyclopædia' says—'As an alleviative in pulmonary complaints, the Iceland Moss is well known,' and of Carragheen or Irish Moss, 'It is a marine plant which grows upon the rocks of the Northern Coast of Europe, especially of Ireland, and is collected for the preparation of a light and nutritious food. It is particularly recommended in pulmonary and many other affections,' &c., &c. A syrup made with Sea Moss Farine, sweetened and flavoured to taste, will be found a specific in all ordinary cases of cough."

The Sea Moss Farine, when placed under the microscope was found to be comminuted Carragheen moss (*Sphærococcus crispus*). It seemed to be cleanly prepared, free from the natural impurities, which frequently consist of sand and effloresced sea salt, and sometimes clear small shells. It gave 1·28 of an ash, which chiefly consisted of chloride of sodium, with a trace of iodide.

The composition of Caragheen moss, according to Herberger, is—

Gelatinous matter	79·1
Mucus	9·5
Resin . , ...	·7
Chloride of sodium . . .	1·3
Chloride of magnesia . . .	·7
Skeleton (consisting of cellular substance and salts) . .	8·7
	100·

This analysis, however, will hardly convey the fact that Carragheen moss contains a very considerable amount of amylaceous-like matter. We need hardly remark that the first part of the advertisement referring to Iceland moss has nothing to do with Carragheen moss, and why it is introduced there we cannot comprehend. Iceland moss is a perfectly distinct product from Irish moss.

Like many others of American introduction, it was much too loudly heralded, and its *marvellous qualities* fail to find favour with the Profession and the public.

(*To be continued.*)

The Medical Press and Circular.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, MARCH 13, 1872.

THE MEDICAL COUNCIL.

The General Medical Council has again met, and has accomplished rather less than its usual small average of work. We do not refer to its talking power which is as well developed as ever. If we could spare the space, or our readers would forgive us, it would be easy to occupy an entire number of the Medical Press with a report of the proceedings; but, inasmuch as we can communicate the result in a single article, we propose to spare our readers the infliction of columns of sterile discussion with trivial interludes. Five days were consumed by the Council, and the printed minutes extend over seventy-two pages. If we get, as seems intended, a second such meeting this year it will be dear enough at the estimated cost of £4,700, or if we deduct the expenses of the Branch Councils, £3,500. Last year the General Council only held one meeting, and spent £2,931 2s. 10½d. the expenses of the Branch Councils, adding £1,126 18s. 10d., which made a total expenditure of £4,058 1s. 8½d.

From this it is clear enough that the Council is not a cheap machine, though if it had done a tithe of what it was expected to do, or half what it could easily have done, we should have been thoroughly content.* As it is this year has been perhaps a more contemptible *fiasco* than ever, and it is high time to put the monetary question prominently forward.

We may put aside the fact that the Council received several letters, and ordered them to be put on the minutes and formal answers sent, as one requiring no great exercise of corporate capacity—as indeed a function that would have been quite as easily discharged by a clerk. A resolution to prosecute or not to prosecute a person accused, is not a very onerous affair. The appointment of committees and other formal business may pass, as may the votes of thanks, and so on. The one subject of debate—the single object of the meeting—was to receive communications from the medical authorities of the three kingdoms respecting Conjoint Boards.

The position of this question is pretty well known to our readers, who have been, from time to time, informed of the progress of the negotiations carried on in accordance with the desire expressed by the Council last year. Well, the Council met as we have said to consider the three schemes, and the result we have to report is, that the said schemes have no existence, and, moreover, after this may probably be further off than ever of realisation. What then was done? The Council expressed an approval of one incomplete scheme, and adjourned until July. The resolution states that the Council "hopes that a scheme for a conjoint examination which it will be able to sanction, may be submitted to the Council by the 1st of July, 1872." Was ever a more ridiculous position for a controlling body? Considering that its recommendations and hopes have hitherto been useless, that it has never ventured on any stronger terms, much less the "stronger measures," the very mention of which horrified some, we would suggest that the Council at least spare us the expense of another meeting until its "hopes" have become realised. In July it can do nothing but pass a resolution, and so far as the Council is concerned another year may be considered as wasted. Nothing but legislation can deliver the Profession from the incubus under which it groans, or put a stop to the cry for Medical reform. The Council has been tried and miserably failed.

The nearest approach to a Conjoint Board that has been made, is undoubtedly the scheme of the two London Royal Colleges which we have already laid before our readers, and the merits and defects of which were brought out in the discussion at the Council with sufficient clearness. In alluding to it as incomplete, we have implied its greatest defect; but we are anxious to acknowledge that this is not altogether the fault of the Colleges. The task was not easy. All who know the slowness with which old institutions move, or who have watched the doings of the various bodies, or their response to the cries of the Profession, may readily admit that its preparation is something at which we might almost express surprise.

But the Royal College of Physicians of London has lately made much progress, and may now fairly lay claim to a front rank among our corporations, for it has carried out valuable reforms, and we yet hope great things of it. Further, the Universities of Oxford, Cambridge, and Durham, will act with the two colleges—a most important fact. The London University approves, but is said to be fettered by some legal difficulty. We do not think much of this, but the Home Secretary, who is not strong enough to think on such matters for himself, has taken advice, and under it declines to sanction the restriction required. We have no doubt that the University will be able to find a way to compel all its graduates to face the Conjoint Board, should it ever be in full working order—a thing about which we have considerable doubt.

But the Apothecaries' Society is in a more awkward predicament. It is fettered by an Act of Parliament; but this, at the same time, gives it undoubted power to confer its license without the co-operation of any other body, and this diploma entitles the holder to admission to the Register. The greatest legal difficulty we see is in regard to apprenticeship. Surely, the mere examination in surgery is a point that could be got over. Do the colleges desire to act with the Society, or would they rather snuff it out? If so, it should be remembered that there are other diplomas that would give the holder a surgical qualification, and in conjunction with one of them the Hall might hold out a long time, for it is a cheap license. We should regret this, and we have not much sympathy with the notion that thirty guineas is too much for a license to practice our Profession. The lawyers pay much more in mere stamp duty.

It seems then clear that the English scheme—which is the most advanced—is incomplete. With one body left out, the Conjoint Board is unrealised, and the carrying out of the plan means merely such a combination of two bodies as was years ago carried out in Scotland and which seems to give satisfaction. Only the Universities have agreed to recognise this union of the two bodies, and take the examination as a part of their requirements—a sensible example which the Scotch Universities would do well to follow. But then the door is left open for other entries to the Register, and we are only one step nearer to the position desired. Still, one step is something, though that ought to have been attained years ago.

The London College of Physicians can, it is said, in a single license, confer the right to practise medicine, surgery, and midwifery. The decision that its diploma was also a surgical qualification put all in its power, and if it had had the courage it could have become the general portal to the Profession. Suppose the Apothecaries' Society had an equal power. It could then stand alone and beat all competitors out of the field. If any surgical corporation capable of admitting to the Register would act with it, it could hold out against the scheme under consideration. If it could but get a new act enabling it to examine and license in surgery also, its one diploma would be the most complete, and the cheapest. We do not say there is a danger of this, but it shows how involved the question is, and it leads us to the conclusion that legislation is required to accomplish what so many profess to desire.

For other reasons, too, as we have often shown, legislation is needed. But if this is to be resorted to, why not let it be thorough and complete? We want no tinkering. Let us encourage no more piecemeal legislation. Let the interests of corporations be no longer placed before the interests of the public and the Profession. Give us a sound act—one efficient Medical Reform—extending to every licensing body in the three kingdoms, and embracing also the General Medical Council itself.

Nothing short of the wisdom of parliament is competent to cope with the contending interests of the corporations, or to place Medical politics on a satisfactory basis.

MR. MUNTZ'S ADULTERATION BILL.

The measure which now lies on the table of the House is, perhaps, the only attempt to check trade frauds which the circumstances of the country and the influence of the shop-keeping class will at present permit but, should it become law, it certainly will not effect any real reform in the time-honoured and legitimised system of trade roguery which now exists nor will it remove to any extent the difficulties which at present prevent the perpetrators of these frauds from being brought to justice. The pith of the Bill is in the following clauses, of which we quote the important parts *verbatim*:—

Every person who shall wilfully admix, and every person who shall order any other person or persons to admix, with any article of food or drink, any injurious or poisonous ingredient or material to adulterate the same for sale, and every person who shall wilfully admix, and every person who shall order any other person or persons to admix, any ingredient or material with any drug to adulterate the same for sale, shall for the first offence be liable to forfeit £50, and costs, and for the second offence be imprisoned for six months, with hard labour.

Every person who shall sell any article of food or drink with which to the knowledge of such person any ingredient or material injurious to the health of persons eating or drinking such article has been mixed, and every person who shall sell as pure and unadulterated any article of food or drink, or any drug that is adulterated or not pure, shall pay a penalty not exceeding twenty pounds, together with costs; and for a second offence it shall be lawful for the justices to cause such offender's name, place of abode, and offence to be published, at the expense of such an offender, in such newspaper or in such other manner as to the said justice shall seem desirable.

Vestries in London Courts of Quarter Sessions and Town Councils in England and Ireland, may appoint one or more persons possessing competent medical, chemical, and microscopical knowledge as analysts of all articles of food, drink, and drugs, and shall pay to such analysts such salary or allowances as they may think fit.

The inspector of nuisances, or weights and measures, or of markets, as the local authority shall determine, may procure and submit samples of articles of food or drink and drugs suspected to be adulterated to be analysed by the analysts appointed under this Act, and may cause a complaint of an offence against this Act by the party selling or adulterating such articles of food or drink or drugs to be made before a justice of the peace.

The analysts shall report quarterly to the local authorities appointing them the number of articles of food, drink, or drugs analysed by them under this Act during the foregoing quarter, and shall specify the nature and kind of adulterations detected in such articles of food, drink, and drugs, and all such reports shall be read at the meetings of the local authorities appointing such analysts.

Any purchaser of any article of food, or drink, or drugs, shall be entitled, on payment of a sum not less than one shilling or more than five shillings, to have any such article analysed by the analysts.

The expense of executing this Act shall be borne in the counties out of the county rate, and in boroughs out of the borough fund.

These clauses unfortunately retain all those phrases which have rendered abortive previous attempts at adulteration legislation, and unless they be modified they will certainly not give any increased facility for the punishment of fraud. Firstly, it is declared that any person who wilfully adds a "poisonous or injurious ingredient" to food or drink, or *any* foreign ingredient to a drug for the purposes of sale, shall be punished. Secondly, that any person who, with knowledge of the fact, shall sell any food and drink or drug so adulterated, or who shall sell as pure any article known to him to be impure, shall be punished. Thirdly, it is provided that local authorities *may* appoint and pay a staff of officials to buy samples, analyze them and prosecute offenders.

Surely such provisions cannot be honestly meant to prevent adulteration. Let us anticipate their working as law, judging by our experience of town councils, uneducated shopkeepers, and sharp manufacturing firms. Is it likely that any number of town councils—mainly constituted of shopkeepers and, if not, elected as the representatives of shopkeepers—will put the ratepayers to the expense, and involve themselves in the responsibilities of eternal prosecutions against their own class and their own constituents? Surely Mr. Muntz knows well that, as regards the appointment of analysts and inspectors, *may* means *won't*, and that the permissive power on which he depends for the carrying out of his Bill, and which has been so earnestly condemned by the Royal Sanitary Commission, practically excludes nine out of ten districts from its operation.

Suppose, however, a town council like that of Dublin, which has appointed its analyst and staff. Mr. Inspector Sharp buys a tin of "fine" mustard from old Mrs. Mulowney's huxter's shop, which the analyst finds to be a just mixture of flour, turmeric, perhaps chrome yellow and mustard refuse. Mrs. Mulowney receives her invitation to attend the police court. She pleads truly that she did not mix the mustard—that she bought it from the traveller of Messrs. Chisel and Do four years ago, since when it had been lying in her window—that she neither knew nor wanted to know what it was made of. Of course the poor ignorant old woman cannot be punished, and as there is no evidence of the sale to her by Messrs. Chisel and Do they cannot be reached either. But suppose Mr. Inspector Sharp keeps watch and secures a package of "fine" mustard from the same firm with the invoice, and the evidence of the retailer who bought it to help in bringing the adulteration home to them. The prosecution is instituted, and the attorneys of the firm take defence. Here are a few of their pleas :—

That the firm never sold the mustard.

That, if they did, it was pure when they sold it, and must have been adulterated since then.

That it contains no adulteration, except what is unavoidable in the process of manufacture.

That, if it was adulterated when sold, they had no knowledge of the fact, and, therefore, they are not liable.

That they did not adulterate it *for sale*.

That the addition to it is not a poisonous or injurious ingredient, within the meaning of the Act.

That they did not sell it as pure, but only as "fine," and therefore are not liable,

It must be obvious that with such loopholes as the Bill affords, prosecuting to conviction would be almost a hopeless duty, and as the retailer could not be proved to have guilty knowledge of the fraud, and the manufacturer could not be made amenable, the Bill would be either a dead letter or a protection to trade roguery.

The question will never be solved until the retailer is made absolutely liable. No doubt he would, in many instances, be innocent of knowingly selling adulterated goods as pure, but, if so, he would have his remedy either in handing over the adulterating firm to justice, or recovering damages from them for the loss sustained by him by his being prosecuted. In one month manufacturers would learn that the risks of such tricks were greater than the profits. Should Mr. Muntz's Bill pass, the public will have to bear in mind that if they want a pure article they must see that it is labelled "pure." Such epithets as "fine," "superfine," "extra superfine," "best," "superior," &c., have no meaning, and, as a fact, are now used to cover all sorts of sophisticated trash.

To us, in view of these facts, Mr. Muntz's Bill looks rather more like a *ruse*, and a demonstration of zeal in the cause, than a honest effort to protect the public against the frauds, of which, in the smallest domestic matters, they are the daily victims.

Since the foregoing remarks were written, Mr. Muntz's Bill has been read a second time *pro forma*, on the understanding that its objects are to be effected by Mr. Stansfeld's Public Health Bill, and that it is not to be proceeded with unless the latter measure be withdrawn.

In moving the second reading Mr. Muntz took pains to justify the verdict on the Bill which we have given above.

> He "was pleased to be able to observe that the subject had excited much greater interest than it did formerly, and that people had begun to recognise the fact that it did not propose to interfere with the nefarious practices of trade, but to put a stop to the adulteration of food by the mixture of articles poisonous or injurious to health. If any one choose to mix beans with coffee or water with milk, no one under this Act could say anything; but if any baker adulterated his bread with brick-dust, poison of any sort, or with plaster of Paris, the clauses of this Bill would render him liable to severe punishment."

Considering that nine hundred and ninety-nine adulterants out of each thousand could not be proved to be poisonous in the quantities used, and that Mr. Muntz's clauses afford a complete protection to the guilty party in the thousandth case, it is not using too harsh a term to designate the Bill a *ruse*.

◆

SCOTLAND.

EDINBURGH.

The members of the University Dramatic Club gave a most successful entertainment in the Theatre Royal on the 4th, the proceeds being devoted to the Royal Infirmary. The entertainment is to be repeated on the 15th, for the benefit of the Sick Children's Hospital.

GLASGOW.

Professor Gairdner delivered an address to the members of the University Society on the evening of the 4th, taking as his subject the relation of teaching to examination.

> Examination, he considered, had a double function. It might be regarded, in the first place, as a system of policy for dismissing or rejecting or eliminating incompetent or ill-instructed men; and in the second place, it might be regarded as a distinct system for regulating the results of education so as to make these felt by the learner and the teacher alike throughout the process of education. By leaving out of sight one of these functions, examination must be considered as to some extent defective in relation to its whole purpose. His object, in the first place, was to show that of these two functions the second—viz., that which regards examination as a

final process, influencing the whole process of teaching, and not merely a police process for diminishing incompetent men; he said that of these two functions the second was by far the most important, and that every movement that tended to divorce those two objects of separate examination or part of educational machinery was to be discouraged, as tending in course of time to the serious detriment of education; and by education he meant not merely knowledge, but training, as the etymology of the word implied—not merely the acquaintance of facts, but character formed and ripened through the influence of study. It was this latter aspect of examination—it was this view of education—which was to be influenced by examination, that a member of a University was above all other men bound to protect and defend to the best of his ability, and if he found that the political movements of the time or the current of general opinion were running in a direction adverse to sound education in the higher sense in which he had advocated it, he was bound to interfere, effectually if he could, and if he could not do so, then, at least, he was bound to protest and to stand clear from any conflict in such a movement. He believed that the Medical Council of Education and Registration was at the present moment engaged in a most dangerous experiment—one which had only very superficial benefits to recommend it, and many latent evils, not the least of which would be found to be its arbitrary interference with the Universities of Scotland, and with the teaching bodies all over the kingdom. He maintained that, by the proposal of the Medical Council to have three boards—one in England, one in Scotland, and one in Ireland—it was impossible that there could be a uniform line which divided between good and the bad. Even if they were to admit for a moment that it was possible, theoretically, to do so, even if they were to admit that they could take the branches of medical knowledge, and deal them all out in this fashion—so much physiology, and such and such answer shall be "pass," whereas the inferior answer shall be "reject,"—even if they could bring that into the medical examination, they still had lying behind that the difficulty that these same examiners, applying the same process to a great number of men in succession, would lose their delicacy of appreciation in the process. An examination which was founded on the idea of merely establishing a uniform standard for the whole kingdom, must in the very nature of it be a fallacy, and must break down in practice. Now, although the Medical Council was not at this moment precisely proposing to have one Board of Examiners for the whole kingdom, they must not forget that the proposal of the Medical Council had another within it, and that it was under the threat of Government interference that the Medical Council had taken up the idea of a conjoint board for Scotland, England, and Ireland. Believing as he did that uniformity was impracticable in the first place, the second question was, supposing it practicable, was it desirable? There he ventured to take issue, and to take exception to the doctrine which was at present circulated in various quarters—that uniformity was desirable. He did not think it was, and held that a uniform qualification for the whole country must of necessity be a low qualification. The present system was that nineteen bodies granted a licence to practise, and of these some only prefer to grant what might be called a sort of minimum licence, while others, as the Universities, granted a higher degree of diploma. That was the system which had come down to them. He did not say that it was free from faults, but he said it was a system which was interwoven in the history of the country, which had sustained the medical profession hitherto, and which ought not to be rashly interfered with and superseded, unless they could show solid advantages to be attained, and unless they could prove that advantages would not be counteracted by still greater drawbacks.

◆

Notes on Current Topics.

Sanitary Inspection.

Considerable alarm has been expressed lest Mr. Stansfeld should be induced to resort to the plan of inspection by gentlemen destitute of Medical knowledge. Such a blot on his measure would deserve to cause its defeat. We all know that lawyers have a knack of thrusting themselves into all manner of offices, but in the present state of public opinion, to confide to them the inspection of sanitary measures would surely bring ridicule on any minister. No one but a Medical man can be competent for such a post. We never thrust our Profession into legal matters, and we hope the lawyers will refrain from further raids into ours. The *Standard*, which has lately given much attention to sanitary subjects, has been emphatic in endorsing the view that all Medical men maintain. That paper has also very carefully examined the points of divergence between the Government bill and that of Sir C. Adderley. The latter is a consolidation bill, and we should be glad if those clauses were adopted by the Government, for we sorely need consolidation.

The Sewage Question.

Perhaps this is the greatest sanitary question of the day. We have, therefore, much pleasure in stating that the invaluable Reports that were issued last year in the Medical Press and Circular are now once more accessible to all. The numbers containing those Reports rapidly went out of print, and Messrs. Baillière, Tindall, and Cox have now brought them out in book form. They make a very handy four-and-sixpenny volume; the writers have carefully revised them throughout, and made several important additions. As our readers are well aware, the whole of the chemical analyses were made by Dr. Letheby, and in other departments the book is one of indisputable authority. No one, therefore, in the least interested in the sewage question—and who is not—should fail to read it. A careful consideration of its contents should precede investment or other action in reference to sewage, and no one can profess to understand the sewage question who has not carefully considered the contents of this volume.

Did Syphilis come from America ?

Readers of the Medical Press and Circular may be interested in hearing what is said in America about the asserted origin of syphilis in the New World. The following occurs in the *Medical and Surgical Reporter*, Philadelphia, December 16th, from the pen of the editor:

"This famous historical question, which everybody thought had been settled long ago in the negative, has recently been reopened with a powerful array of arguments in the affirmative by Dr. Alfred Fournier, of Paris, Dr. Ferrari, the well-known surgeon of Paris, and Dr. Charles Drysdale, of London.

"The latter, in a general summary of the arguments which he confesses have worked his own conversion from an opposite view, says, in the Medical Press and Circular for October 25, 1871, after disposing of all the alleged cases of syphilis described in sacred and profane ancient history:

"'Whence, then, did the disease come to us? Although the Americans accuse the Europeans of having carried this disease to them, nevertheless, according to the opinion most universally adopted by the learned men in the Congress of Nantes, in 1835, it would seem that it is a disease of very ancient origin in America, and that, according to Bechi and Sanchez, it came to Europe only at the end of the 15th century, brought by the companions of Columbus. And there is, indeed, a most powerful argument to prove this in Columbus himself, who asserts that, when he returned the second time to the New World, he found among the Spaniards who had been left there, to study the manners of the savages, a monk, who, having learnt their language, was able to tell him what he had observed, and particularly the fact that, among the Indians there existed very commonly a disease they called *caracaracol*, and which showed itself as a scab over the body.'"

"The point in the above narration of events which we propose to examine at present is, whether the disease referred to by the monk left by Columbus, under the name *caracaracol*, was syphilis or not.

"This monk's name was Roman Pane, a Catalan, and a lay brother of the Hieronymite Order. He was an illiterate man, and knew but slightly one of the three languages in San Domingo, where he was left by Columbus. During his stay he collected the ancient traditions of the natives, and wrote them down in Spanish. One of these traditions relates that the earliest of the human race were created all males. They searched for women but found none. One day, however, they perceived certain creatures, with slippery skins, who ran with great swiftness, and who slipped from their grasp when caught.

"To retain them, the men chose four of their number, who were *caracaracol*, because these had their hands rough and could hold on to whatever they grasped. The *caracaracol* is a disease like the scurf (*comme la gale*) which makes the body very rough.

"This description cannot rightly be applied to syphilis, but rather to any of the furfuraceous diseases of the skin. The fact that the disease appears on the inner surface of the hand also serves to show that it is not likely to have been syphilis.

"The word *caracaracol* is derived from *caracol*, a small univalve shell with a rough surface, and refers to the roughened appearance of the surface on the disease. The same word is now used in a modern form by the Arawack Indians of Guiana, who speak the language spoken by the native of Hayti at the time of Columbus, but it is *not* by them confined to syphilis, but means any sickness.

"Brother Pane, we may add, devotes several chapters of his narrative to describing the native physicians, the herbs they used, and how they cured their patients. As he presented his reports to the Admiral at his third voyage, and after the syphilis had broken out in the Spanish army and navy, it is highly probable that it was supposed to have been caught from the native women, he would have said something about it.

"Without expressing any opinion on the other branches of the question under discussion, we confidently assert that no evidence has yet been brought forward that the American Indians were acquainted with syphilis before it was introduced among them by the European settlers."

Health of Dublin.

In the Dublin Registration District the births *registered* during the week ending 2nd March amounted to 181. The average number in the corresponding week of the years 1864 to 1871 inclusive, was 183. The deaths *registered* during the week were 183. The average number in the corresponding week of the previous eight years was 183. Thirty-seven deaths from small-pox were *registered* during the week, against 33 in the preceding week, and 45 in the week ended 17th February. Seven deaths from small-pox (City cases) occurred in the North Union Small-pox Hospital. Three deaths from this disease were *registered* in Belfast, and 27 in Cork. Fever caused 9 deaths in the Dublin Registration District, viz.: Typhus, 4; typhoid, or enteric, 2; and simple continued fever, 3. Four deaths resulted from scarlet fever, 2 from diarrhœa, and 1 each from measles and whooping cough. Sixteen children died from convulsions. Three deaths were ascribed to paralysis, 3 to epilepsy, and 1 to apoplexy. Eighteen deaths resulted from bronchitis, and 6 from pneumonia. Bright's disease caused 2 deaths, jaundice 1, and liver disease 1. Heart disease proved fatal in 11 instances. Twenty-one deaths were caused by phthisis, 4 by mesenteric disease, 2 by hydrocephalus, and 1 by scrofula. Two accidental deaths were registered.

Oxysulphate of Iron.

Dr. George D. Hodge remarks in the *Georgia Medical Companion* that our best iron compounds are those having the *red oxide* as their base; and especially is *this* true, when our aim is the restoration of impoverished blood. In *this* consists the efficacy of most mineral waters, as well as the advantages of the oxysulphates, over many others. The first formula is no *novelty*, but was used by Sylvester sixty years ago:

℞ Crystallised Sulphate Iron, dr. ijss.;
Nitric Acid, dr. iij.;
Pure Water, oz. iss.

Stir well the iron and acid, by constant rubbing in a glass mortar, for at least, 20 minutes—gradually add the water, and filter through white filtering paper. The result is a clear limpid fluid, which may be given in doses of from 5 to 10 or 15 drops, twice daily, in a little water or infusion of quassia—is easily prepared, and will be found, for general use, preferable to the muriated tincture of the shops—harmonises chemically with, and confers solubility on quinine, sulph. magnesia, &c., and may be relied on as one of the very best restoratives for debility and torpor of the liver, following successfully treated cases of hepatitis, or miasmatic fevers, in which the biliary organs have suffered. In malarial diseases Dr. Hodge states:

℞ Sulph. Quinine, grs. xxx.;
Liq. Oxysulph. Iron, dr. j.;
Fowler's Sol., dr. j.;
Water, oz. ij. ♏

S.—A tea-spoonful thrice daily, after meals, occasionally adding a small dose of sulph. magnesia to obviate costiveness. The iron and arsenic may be varied to meet the leading indication:

℞ Spts. Mindererus, oz. ij.;
Liq. Oxysulph. Iron, dr. j. ♏

This gives a beautiful florid mixture—palatable, and in doses of a tea-spoonful or so, thrice a day—not apt to disappoint as a general tonic. The ammonia promotes the action of the iron and imparts to it a decided *capillary and renal tendency*. We have found the liqnor oxysulph., in doses of from 3 to 6 minims with a drachm or two of the liquor ammonia acetat, every 3 or 4 hours, a valuable remedial agent in combatting the forming stages of tonsilitis, scarlatina, typhoid fever, and puerperal inflammations. In these affections, I am convinced of the efficacy of this combination as superior to the mur. tinct. used in the same way.

SYRUP IODIDE IRON.

℞ Iod. Pot., grs. xxx.;
Liq. Oxysulph. Iron, dr. ij.;
Simple Syrup, oz. j. and dr. ij. ♏

Dissolve the iodide in the syrup and add the iron. This syrup is of a beautiful red colour—will keep without deposition for years, and is a *most excellent tonic and alterative*, in doses of 20 to 60 drops twice a day. We will close by adding, if the brom. pot. or brom. ammonia be substituted for the iodide (correspondingly as to quantity) in the above formula, a rich golden coloured compound will result and prove itself on trial, a remedy of the first class in all anæmic, chlorotic and nervous conditions resulting from uterine affections or otherwise.

Nitro-muriatic Acid in Small-Pox and other Zymotic Diseases.

The Editor of *Medical Cosmos* writes in his journal :— The prominent indication in the preventitive and curative treatment of all contagious diseases is to destroy the infecting poison and disinfect the body. In general, the vegetable and mineral acids are very useful for this purpose, particularly the carbolic, sulphurous, hydrochloric, and nitro-muriatic. The last is especially potent, not only in the milder disorders of an infectious and zymotic character, but also in the more malignant, as typhus fever and small-pox. In fact, both as a preventitive and corrective of these, it seems to exert a specific influence In small-pox, nitro-muriatic acid appears to be quite efficient as a prophylactive and curative agent in aborting the disease altogether, when given in time, and cutting it short after its inception, by breaking up the primary fever, preventing the eruption, checking suppuration, drying up the pustules, disinfecting the body, and destroying the noxious emanations. It possesses antidotal, antiperiodic, antiphlogistic, antizymotic, antipyretic, antiscorbutic, antihæmorrhagic, antiseptic, antipyic, disinfectant, depurant, alterative, nutrient, and tonic properties, and is very efficacious in the preventive and curative treatment of infectious, zymotic, and contagious diseases. It may be given, in conjunction with other compatible remedies, with advantage, and be administered as freely as the system will tolerate, in doses proportioned to the necessities of the case, as often as required. In water or lemonade, sweetened to taste, it forms an acceptable and refreshing beverage, very agreeable to those suffering with scorbutic or febrile affections. To protect the teeth, it should be taken through a glass, porcelain, or other non-metallic tube, and the mouth be rinsed out subsequently with alkaline or plain water.

H.R.H. The Prince of Wales.

The Prince and Princess left London on Saturday, arriving in Paris in the evening. H.R.H. was not much fatigued by the journey. It is understood that he will stay in the French capital for two or three days ; travelling thence to Geneva, *en route* for the shores of the Mediterranean and the south of France.

Conversazione of the Medical Society of London.

On the 5th instant, a *conversazione* was held by the members of this Society and their friends, at the invitation of Dr. Andrew Clark, the distinguished president: There was a brilliant gathering of the most eminent of the Profession, and the splendid rooms in Hanover square were graced in addition by the presence of a large number of ladies, whose bright looks and tastefully-superb dresses gave additional lustre and animation to the scene.

The tables were covered with objects of interest, arranged for the amusement and gratification of the visitors. An ample supply of refreshments enabled the guests, without fatigue, to continue the inspection of the treasures collected for their delight until past midnight.

The proceedings were further enlivened by the inspiring music of the band of the Royal Artillery, and the company separated at last with happy faces, and with the universal admission that three more agreeable hours had seldom or never been experienced.

Dr. Quain will lecture at the Royal College of Physicians of London on March 15th, 20th, and 22nd, "On Diseases of the Muscular Walls of the Heart."

In the metropolis last week, 1,423 deaths were registered, being 212 below the average. The mean temperature of the week was 5·6 deg. above the average of the corresponding week in fifty years.

On Monday morning the daily papers announced that Mazzini was preparing a revolutionary invasion of Italy from one of the Swiss cantons. On Tuesday (yesterday) morning, a telegram announces the sudden death of this celebrated Italian.

Dr. H. S. Purdon, of Belfast, Physician to the Hospital for Skin Diseases, late editor of the *Journal of Cutaneous Medicine*, and now editor of the "Quarterly Report on Dermatology" that appears in our contemporary, *The Doctor*, has been elected a Corresponding Member of the New York Dermatological Society.

The Fothergillian Gold Medal of the Medical Society of London has been awarded by the Council to Dr. Edwards Crisp for his essay on "Croup." One of the two silver medals is given to Dr. Thorowgood for services rendered to the Society as secretary, and the other, which is always awarded to a gentleman not a Fellow of the Society, to Dr. Silver, for his paper on "Mitral Stenosis."

Dr. W. Handsel Griffiths is a candidate for the Chair of Botany in the Royal College of Science in Dublin. Dr. Griffiths is the author of "A System of Botanical Analysis applied to the Diagnosis of British Natural Orders," and obtained the degree of Doctor of Philosophy in Gottingen University for a memoir on "Hæmodynamics," and is now Assistant Librarian in the Royal College of Surgeons in Ireland.

At her Majesty's Levee held last week, the following members of the Profession had the honour of presentation : Sir William Gull, M.D., F.R.S., the Director-General of the Medical Department. Doctors : Wm. Gill, F. W. Innes, Peter Leonard, D. McEwan, R. D. Mason, C.B., Ivor Murray, T. Rudd, A. Crocker, A. Watson, J. Chatterton, W. Dickson, R.N., W. F. Domville, R.N., J. D. McIllree, G. K. Hardie, Murray, Pickford, Routh, Sull, Swettenham, Giuse, and Helsham. Messrs. W. H. Price, A. C. Ross, G. White, W. O'Halloran, McCormac, H. J. Hayne, &c.

There is at the present time a person who appears to be going the round of rural places and villages, under the name of Dr. Sexton, a travelling agent to the Anti-Vaccination League, holding forth by lectures and otherwise against the Vaccination Act, and inciting the public against its enforcement. We observe that at some of these lectures, members of the Profession have attended to rebut the accusations brought forward. We would, however, caution our brethren to first ascertain that this individual is a foreman worthy their steel. Dr. Sexton may be a very respectable man, but we fail to find his name where, as a qualified Medical man, it should be.

The Government Public Health Bill comes before Parliament to-morrow (Thursday) evening for the second reading. It is understood that the leading feature of the measure is the centralisation of the powers of the various local boards of the country in the London Local Government Board, with direct personal communication in place of the present correspondence. This personal communication will be obtained by means of travelling inspectors—who will, we presume, be selected from the ranks of the Profession—at salaries from £600 to £800 a year, and whose duties will be to visit the various localities at stated intervals, and report upon hygienic and sanitary matters generally.

SPECIAL REPORT
OF THE
DISCUSSION ON THE
CONTAGIOUS DISEASES ACTS
AT THE
MEDICAL SOCIETY OF LONDON.

We have previously given special reports on the Royal Commission on the Contagious Diseases' Acts, and have, on many occasions, been compelled to refer to this disagreeable subject. It is our wish to give free scope to discussion, and to avoid the vexation caused by one-sided leading articles. The last really important event has been the remarkable discussion at the Medical Society of London, where both sides were heard. We proceed to give a special report of the proceedings, from notes taken at the time.

A crowded meeting of the Medical Society was held on Feb. 19th, 1872, Dr. Andrew Clark in the chair, to hear a paper by Dr. C. Bell Taylor, of Nottingham, on "The Statistical Results of the Contagious Diseases' Acts."

Dr. Taylor said that the only trustworthy bases for ascertaining the effects of the Contagious Diseases' Acts, are the returns made from time to time to Parliament. Such returns are contained—1. In tables contained in the Appendix to the Report of the Lords' Committee on the Acts, in 1868. 2. In Tables contained in Report of Commons' Commission, in 1869. 3. In Tables of a Return to the Commons by Mr. Mitford, in 1870; and 4. Tables given in the Appendix to the Royal Commission, in 1871; besides which there are the Army and Navy Reports published annually. On page 815 of the Report of the Royal Commission, it seems that, in the whole army, the number of men "constantly sick from enthetic diseases" was 16·00 per 1,000, and in 1869 it was 14·87 per 1,000, or 1·13 per 1000. For the navy, on page 816, it seems that in the navy at Home Ports, there were 101·3 cases of venereal disease per 1,000 in 1866, and 101·9 per 1,000 in 1869. Mr. Mitford's tables were most misleading, but had been quoted by large numbers of newspapers. It had been stated that the operation of the Contagious Diseases' Acts had reduced venereal disease, among the army, from 120 cases per 1,000 to 54 per 1,000. This is simply untrue, as indicated by the foregoing figures. These statistics given by Balfour only refer to one group of venereal diseases, and refer only to some stations where the Acts are carried out. Of the whole 28 stations where troops are stationed, Dr. Balfour's tables only relate to two. There is quite as much gonorrhœa in the army as there was in 1866,—nay more. The statistics of 120 primary sores per 1,000 in 1865, and 54·5 per 1,000 in 1870, are most incorrect; since the figures for 1865 were taken from only two stations, and those for 1870 from fourteen stations. The figures for all stations in 1865 were actually under 100, and a great reduction was noticed before the Acts came into operation. At Windsor the number of cases of disease has never been so low since the Acts were introduced as before. Tables were pointed to on the wall, which had been drawn up by Dr. Hoopell from the Army Medical Reports, which showed that, in 1866, the number of men per 1,000 (out of nearly 60,000) affected by venereal true syphilis, was 23·39; whilst in 1869, it was 26·33. Primary syphilis, in 1866, was 78·53 per 1,000, in 1869 it was 78·72; gonorrhœa in 1866 was 98·43, in 1869 it was 103·11. Other enthetic diseases, in 1866, were 36·19; in 1868, they were 37·88. In the whole army, the total number of admissions in 1866 was 258·5 per 1,000; in 1868, 282·2 per 1,000.

Dr. Clark (the President) said it was very difficult to keep the emotions under subjection when treating on subjects; but he hoped all would do so. The conditions of the discussion were ten minutes for each speaker; no member to speak twice.

Mr. Lane congratulated Dr. Taylor on the subdued tone of this paper; which paper was entirely a statistical one. He was not going to attempt to answer the statistical arguments made by Dr. Taylor; Dr. Balfour had become convinced by the facts. Windsor, some time ago, had a battalion of Guards, and then had thirty cases of disease in four months. In another four months, in London, there was three times as much in the troops. It was then late in the day to say that these Acts do no good. Within the last few days Mr. Bruce had to repeal these Acts. Well, he could not even say anything against the Acts. Juvenile prostitution had entirely disappeared when the Acts were in force, and there was less disease among the women.

Dr. C. R. Drysdale had always been much opposed to the Acts, but had been rather disposed to admit that they might occasionally in small towns do good to the health of the "single" men who formed our army, who should, however, be allowed to marry like policemen, and as troops did in Switzerland and the United States. But, certainly, Dr. Taylor's statistics showed that disease was more prevalent in the whole army and navy *post* the Acts. Such Acts were absurdities when applied to a whole population, as in France. In Paris it was well known they were a perfect failure, and the real good was done by the 600 beds of the Lourcine and Midi, which were voluntary hospitals. These kinds of Acts tended to increase disease, because they increased prostitution. Lefort told him that there was twice as much prostitution in Paris as in London, in proportion to the size of the cities. Husbands infecting their wives should be liable to be divorced with damages. The State should erect hospital in all cities, for epidemics and infectious and contagious diseases, open to all, and voluntary. This would do good without harm.

Mr. Acton said he could not understand Dr. Taylor's figures, and that Dr. Balfour and he had gone over the figures that morning, which showed that, in 1866, there were 120 cases per 1,000 of primary sores, and only 54 per 1,000 in 1869, in some stations. Gonorrhœa was just as prevalent now, as before; and this was a blessing, as it would prevent persons from resorting to Plymouth for fornication. This ought to disarm the opponents who objected to the Acts on this account. Syphilis has decreased very much, he said, in the protected districts, nearly one-half. In the Belgian army, the proportion of primary syphilis was only 4·7 in 1860, and fell to 1·39 in 1866. In Brussels, there are only 1·39 per 1,000 cases. We shall never prevent cases of gonorrhœa, because some women were liable to take gonorrhœa whenever they had much sexual intercourse; but this was of less importance, of course, than syphilis.

Mr. Henry Lee said that there had been five reports in the past years, and yet we have never been convinced. There used to be a belief that syphilis could only be given by primary sores; and surgeons used to accuse women of being unfaithful. It is therefore our duty not to be hasty, and we err if we advise the legislature on this subject, without due consideration. If these Acts were adopted, in three-fourths of the cases a medical man saw, he would not know whether they were diseased or not. In women who had discharges, no man can say whether they will infect or not. Nothing is more common than for men to accuse a wrong woman. In *true syphilis* you can't tell whether a woman will infect or not. For a few days she will infect a number of men, and then no more. Then the woman will, of course, run away from towns where these Acts are in operation; and thus statistics are absurd.

Mr. W. Coulson.—No one doubts how much syphilis has done of evil. The danger we know; can anything else be proposed? If the opponents of the Acts had any remedy, he would like to hear of it. True, some women may give a gonorrhœal discharge without it being diagnosed; but the majority of members would grant that mucous patches are clear enough. If prostitutes are examined, men are less likely to get true syphilis. If this be good for the military stations, it is good for the whole country.

Dr. Webster remarked that in the protected districts, Mr. Acton had admitted that gonorrhœa had increased. Surely that was against the Acts. Paris had been frequently cited as an example of the Acts working well; but M. Carber says that in three years ending in 1862, the total number of patients in the Lourcine and Midi was, on an average, 14,057; and, in 1869, was 16,747. Thus, syphilis in Paris had rather increased. In Naples, Madrid, and other cities, disease is very prevalent, and prostitution is greatly increased by the Acts. Ruffians and procurers abound, and all sorts of vice.

Dr. Septimus Gibbon abhorred statistics, and did not believe in the views of Mr. H. Lee, who had led him astray often in matters relating to syphilis; since 1867, the guardians in London had power to detain women with venereal if they pleased, but they never did please.

Mr. Berkeley Hill said the paper of Dr. Taylor is much like that of Dr. Hoopell's statistics. Dr. Balfour has omitted constitutional syphilis from the tables. He has avoided such cases, as they might be contracted elsewhere. If sores are diminished, then there will be less syphilis; that is clear. The ratio of constantly sick was in the exposed stations much higher than in the protected. Acton and Balfour both say that the Acts have diminished venereal sores. In Plymouth, the average number of criminals treated in the Borough gaols, in 1862, was 70. Before the Acts were put in force in Devonport, 25 per cent. of the cases in gaol were affected. As to voluntary hospitals, the Winchester Voluntary Hospital was empty before the Acts came into operation.

Dr. Meyers observed that Windsor was the best exemplification of the advantage of the Acts. The curious thing is, that the Acts have not done even more in Windsor. The army and navy are extremely benefited by the Acts.

Mr. Curgenven had obtained very satisfactory results from Shorncliffe. There was only one case of venereal disease in hospital lately.

Dr. Murray, of Hong Kong, was surprised to hear the statistics questioned in this way; it seemed so self-evident. In 1858, Hong Kong was put under the Acts, and he had examined thousands with great benefit to the health of the troops.

Dr. Brudenell Carter thought it remarkable how difficult it was to get people to keep to the question in this subject. He was convinced that the Acts were useful, and that the statistics were in their favour.

After some remarks by Dr. C. Hare,

Dr. Routh remarked that Dr. Murray must have been very able, if he was able to say when a woman was able to infect men. When women have syphilis, their discharges will cause syphilis. He was never sure whether a woman had gonorrhœa or no. Gonorrhœa is a very severe disease, let Mr. Acton congratulate himself or not. He would rather have syphilis, himself, than gonorrhœa.

Dr. Tilbury Fox read some quotations from Dr. Routh's evidence before the Royal Commission; and expressed himself in favour of the Contagious Diseases' Acts in every way.

Mr. Weeden Cooke said that he did not think that there was any diminution in diseases in hospitals in London since the Acts were in force. Examination of men was a disgusting duty, and compulsory examinations were a serious lowering of the Medical Profession.

Mr. Deakin defended his statistics, which were attacked by Dr. Taylor.

The President said that Dr. Taylor had classed together gonorrhœa and syphilis.

Dr. B. Taylor said that Dr. Murray could not have done much for Hong Kong, since the station was said in 1869 (Blue Book) to be in a fearful condition with venereal. His statistics were all genuine, and could be verified. Syphilis was not so bad as some people wished to make out; and it was unfair to destroy the liberty of poor women who now were allowed to go free.

◆

Literature.

SYPHILIS: ITS NATURE AND TREATMENT, WITH A CHAPTER ON GONORRHŒA (*a*).

(*Continued.*)

In Chapter IV., "On Syphilis in Women," the author remarks how frequently mucous tubercles are seen in women. The construction of the female organs, he concludes, is the main cause why hard sores are comparatively so seldom remarked in women, although the absence of induration in woman has been much exaggerated. In cases of malignant syphilis, ulcerations of the genitals of a secondary character in women, may easily be mistaken for soft chancre; but iodide of potassium will clear up the diagnosis very rapidly, and separate these also from scrofula. A woman with secondary affections is almost sure to affect her children whilst the early symptoms are present. Iodide of potassium administered for many months is often followed by perfectly healthy children in women who have gone on having dead births for three or four years.

In Chapter V., the author seems rather to lean to the view of Bœck, that syphilitic parents are apt to have delicate children (scrofulous?) Syphilis is not so malignant a disease now, he thinks, as it was in the fifteenth and sixteenth centuries. Glanders and farcy are diseases bearing great resemblance to syphilis. These kind of diseases look as if there were some virus in the blood, as occurs in the silkworm disease. Scrofula is often very like syphilis, but the scars in scrofula are deeper than those of syphilis, coloured and bridled. The prognosis in infantile syphilis is very grave, however treated, as is well shown by statistics from Bœck, Allingham, Dunn, &c. The author thinks that grain doses of iodide of potassium gives the child a better chance than any other medicament. The disease is very widely spread in London hospital practice, in the author's experience, at the Metropolitan Free Hospital. Secondary symptoms are very frequently contagious and spread the disease, and the blood in the period of eruptions is clearly contagious. It is doubtful whether a mother is ever infected by a fœtus; and also whether a syphilitic father can cause syphilis in the fœtus, unless he first of all infects the mother. Hutchinson's cases are not conclusive on this point. Kissing, examination of women in labour, and sleeping with persons with syphilitic eruption, all are causes of contagion. Vaccine syphilis is a fact and cannot be disputed; but it is very rare in this country. The author quite endorses the views of Mr. Hutchinson as to the occurrence of hereditary syphilis. It is commonly enough met with at Moorfields Hospital. The vast and overwhelming majority of syphilitic children have syphilitic mothers, but in some cases

---

(*a*) "Syphilis: Its Nature and Treatment, with a Chapter on Gonorrhœa." By Charles R. Drysdale, M.D., M.R.C.P.Lond., F.R.C.S.Eng. Physician to the Metropolitan Free Hospital, London, &c. Late Hon. Sec. to the Harveian Society's Commission for Prevention of Venereal Diseases. London: Baillière, Tindall, and Cox. 8vo. Pp. 165.

it cannot be denied that such is not the case. The latter part of Chapter V. is devoted by the author to an account of Dr. Fournier's observations upon syphilitic fever, boulimia, and analgesia, and anæsthesia. All of this part is full of interest, and will be new to many readers.

Chapters VI. and VII. are occupied by a very long account of the views which have reigned as to the treatment of this very important disease. First of all Dr. Drysdale notices that mercury was formerly a kind of panacea for all diseases ; now it is chiefly praised in iritis and syphilis. In iritis much evidence in its favour is adduced from Critchett, &c., and also against it from Williams, Z. Laurence, &c. Mercury was used in syphilis as early as 1497, externally ; and was terribly abused. For a long time it was thought that unless mercury were used all cases of syphilis would go on to a fatal result. Hence mercury was obligatory until, in 1812, experience in Spain showed that syphilis was *usually* a mild disease when let alone. The observations of Rose, Guthrie, Hennern, &c., have shown that it is unnecessary to give such an active drug as mercury for any syphilitic ulcer ; and Thomson, of Edinburgh, showed that it might usuall y be dispensed with in iritis and eruptions among young male adults. Dr. Desruelles, in Paris, and Dr. Fricke, at Hamburgh, treated many cases with mercury and many without it, and preferred the simple treatment, save in very exceptional cases. Ricord remarked that soft sores and gonorrhœa required no mercury ; but said that hard sores required a three months' course of the drug, followed by six months' treatment with the iodide of potassium. This latter drug was introduced into practice by Wallace, of Dublin, in 1832. This was in the author's opinion the most important discovery ever made in drug therapeutics. Mr. Syme has doubtless attributed too many of the lesions seen in syphilis to treatment, and Dr. Hughes Bennett also ; but the author agrees with these gentlemen in accusing mercury with often doing a great deal of damage to syphilitic patients. This is well shown by Professor Bœck's work on the treatment of syphilis, where all kinds of treatment are compared and mercury found to be the worst. The discussion on the treatment of syphilis, in 1867, at the Parisian Société de Chirurgie, showed that many physicians in Paris treated all cases of syphilis with iodide of potassium alone, to the exclusion of mercury.

The author does not seem to think that syphilisation has the power to do much more in the treatment of syphilis than expectation, and not nearly so much as iodide of potassium in large doses. A synopsis of the views of various London authors as to the treatment of syphilis is given, and some remarks about the treatment of infantile syphilis are recorded. Dr. Fournier's views on treatment are quoted at some length, followed by those of Dr. Robert McDonnell, Dr. M. Mackenzie, Dr. Prosser James, and Mr. Allingham. Then come a few formulæ for gonorrhœa and balanitis.

In Chapter VIII. the author expresses his opinion that syphilis is a disease of comparative recent date, and that Columbus brought it into Europe about the beginning of the year 1493. At that time the disease was rapidly fatal in very many cases, and caused the greatest horror and dismay throughout Europe. It is not easy to see how the physicians of the time could be mistaken when they affirmed that it was a " new species of disease." As to soft chancre and gonorrhœa we find notice of both of these among the ancients, but there is nothing like syphilis clearly mentioned by Roman or Greek writers on physic ; as to modern doctrines about the chancre, he leans to the side of Bassereau and the *Dualists*. Gonorrhœa in the male is scarcely ever the cause of syphilis ; Ricord having in 4,600 cases of syphilitic eruption found that ulcers had in a vast majority preceded such. Gonorrhœal pus, too, is scarcely ever inoculable on the person himself. In 1857 Bassereau remarked that syphilis was always derived from persons with syphilitic eruptions, and gave numbers of marks to differentiate the sores which precede such eruptions from other sores. The author avows himself of this school, although it is difficult, he confesses to be certain of our prognosis in some cases of ulceration of the genitals, especially when we have to do with ulcers on the female organs of generation. The " hard sore " however is *usually* quite easily recognised by its long incubation, its want of pus, the hardness of the neighbouring glands, and its healing without any scar. Whether the " soft sore " in any case may be caused by the inoculation of virus on syphilitic patients or not, he thinks that the main theory of dualism is proved, and that " soft sores " are not the same as " hard sores." Syphilis is a disease of the blood, and has only existed some centuries in Europe. Soft chancres have always existed.

We have dwelt thus fully on Dr. Drysdale's work as it now presents us for the first time, in a complete and handy form, an exposition of the opinions of an accomplished physician, who is a recognised authority on all that relates to syphilis. Dr. Drysdale's extensive learning enables him to pass in review the writings of foreign as well as of English syphilographers ; and his candour is impressed on those chapters that treat of disputed points. We know of no other work of its size that is so brimful of information, and we must most heartily recommend it to all who desire a concise treatise on syphilis. It puts the reader thoroughly *au courant* with the latest researches on the subject. We may add that it is well got up, doing credit to the publishers as well as the author. It deserves success, and we should be glad to see it in the hands of every practitioner.

THE PRACTICE OF MEDICAL ELECTRICITY (*a*).

This little treatise gives a concise description of the different forms of galvanic and electro-magnetic machines now in use for remedial purposes. The different diseases in which the application of this agent is indicated are pointed out, and a number of cases successfully treated by electricity are detailed. It is a very useful little book for the practitioner who has not time to study the larger treatises on the same subject.

◆

CURRENT LITERATURE.

CASES OF DIARRHŒA AND CHOLERA (*b*).

Dr. Chapman has the undoubted merit of originating a system of treatment which we believe is of great practical value. We are satisfied of the truth of his assertion that the condition of the viscera of the thorax and abdomen can be modified to a considerable extent by the external application of heat and cold to the spine. We have ourselves observed the advantages of Dr. Chapman's method of treatment in sea-sickness. In the stages of bronchitis where the breathing is dry and tubular, Dr. Chapman's hot-water bag often causes marked relief, and the increased secretion of mucus from the bronchial tubes seems to be proved by the greater softness of the breathing, which may be ascertained to follow in a few minutes by auscultation.

We have never had any opportunities of treating cases of diarrhœa and cholera in the method recommended by Dr. Chapman, but should very much like that a fair trial should be given to them. It appears from the pamphlet under review as well as Dr. Chapman's larger work "Diarrhœa and Cholera" that the author has had considerable difficulties thrown in his way to get a fair trial of his system of treatment. In the pamphlet he gives a summary of the fundamental principles on which he believes his method of treatment rests ; but although we know no scientific objection, fatal to the possible correctness of these principles, we question whether it is wise to try to connect them inseparably with the treatment. Moreover, Dr. Chapman's statements, that cholera does not travel from place to

---

(*a*) "The Practice of Medical Electricity." By G. D. Powell, M.D. Second edition, enlarged. Dublin : Fannin & Co. 1872. 12mo. [illegible] pp.

(*b*) Cases of Diarrhœa and Cholera treated successfully through the agency of the Nervous System, chiefly by means of the Spinal Ice-bag. By John Chapman, M.D., M.R.C.P., M.R.C.S., &c. London : Baillière, Tindall and Cox, 1871.

place, and that it can originate *de novo* in any place in which certain definable conditions co-exist, we cannot subscribe to, at least, in the sense that Dr. Chapman would give to the words.

The clinical basis of Dr. Chapman's treatment is stated in the following paragraphs:

8. "That by means of heat applied along the spine, the general circulation may be lessened, the activity of the glandular system may be increased, and in some cases, of both the voluntary and involuntary muscles may be induced.

9. "That by means of cold applied along the spine, the general circulation may be increased, the activity of the glandular system may be lessened, and cramps of both voluntary and involuntary muscles may be arrested or prevented."

Dr. Chapman gives a considerable number of cases where his system of treatment was successful. We have already advocated a trial of his system in India, ice being easily had in the Presidency towns. It would appear, from a letter published in the pamphlet, that the treatment has been once tried at Calcutta, and with remarkable success. "The natives around me," Mr. Peterson writes, "attributed cure to Jadoo, magic, or the evil spirit, and in that idea I have let them remain."

The pamphlet is in a readable form, and shows both great scientific knowledge and practical sagacity. We have the less difficulty in advocating a trial of Dr. Chapman's system, when we consider that ordinary methods of treatment have yielded very poor results. It has indeed been proved by statistics that the number of deaths following upon seizures of confirmed cholera in India, has rather increased than diminished. The application of cold, in a disease like cholera, may appear somewhat startling. It may serve to overcome this fear when we know that cold applications to the body, and the use of ice-cold body to drink, has been used by the late Professor Niemeyer of Lübingen, who, however, did not seem to be aware of Dr. Chapman's experiments. "With regard to the use of the cold applications, and the administration of ice, I am guided by the patient's feelings, and continue them so long as they are asked for. It frequently happens, therefore, that the patients in the stage of recovery get wearied with these remedies, and leave them off, but in the course of an hour or so greater uneasiness returns than before, and with this, an earnest entreaty for a repetition of the remedies." Dr. Chapman's method of treatment by cold differs from that of the German Professor, in that he confines the application of ice to the spinal region, and uses warm application to the extremities. For the minutiæ of his treatment, on which he lays considerable stress, we refer the reader to the pamphlet itself.

Correspondence.

THE MEDICAL DECLARATION RESPECTING ALCOHOL.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—Of all the fallacies of the Faculty in recent times the Medical Declaration respecting Alcohol seems to me the most egregious and deplorable.

Whether it is penitential or admonitory it is difficult to say, but in either case it is equally unwarrantable. To wash one's dirty linen in public is not less to be deprecated than wantonly to spit upon one's unoffending neighbour. I cannot help thinking that that oracular and portentious document is not a professional bull after all, but only an inflated frog, and that the monster will shortly burst and collapse miserably. Perhaps it is illustrative of that primary instinct to follow your leader with which most gregarious animals and notably sheep, are endowed, that so many hapless victims should have heedlessly rushed through the teetotal trap into the intellectual shambles prepared for them. But the important question is why was this temperance net spread for physicians and surgeons? Are they the chief offenders respecting alcohol "by taking or by giving of excess," or are they in matters of this kind conspicuously unwary, and therefore an easy prey to astute and philanthrophic poachers.

Anyone who surveys society must perceive that doctors are the last men from whom such a declaration should have been required. Magistrates, who licence public-houses, clergymen and benevolent ladies who distribute "Spanish Red" to the sick and infirm, and commercial men, who seal every bargain with a debauch, are surely more dangerous enemies to total abstinence than those who mix Gilbey with their abominable potations, or pour wine over a fevered palate, thereby creating a detestation of alcohol more powerful than the loathing of teetotalism, which its idiotic advocates beget.

But Sir, I have a practical suggestion to offer, or I should not have ventured to address you on this subject. My idea is that the "Temperance Movement," whatever that may be, should direct its attention at once to the cooks and kitchen-maids of this great country. They are the chief instigators and abettors of these drinking customs, which, as the pamphlets tell us, bring misery and ruin on thousands. Their aim seems to be to create varied and multitudinous cravings for alcohol in many forms and disguises. Their greatest achievement are those which are provocative of a thirst that cold tea and lemonade can never quench. And not only so, but all their productions are obtrusively or insiduously tinctured with alcohol. A stream of alcohol trickles through every *menu*. A subtle alcoholic influence gives its charm to every course. The soup with which we commence our repast is redolent of sherry. The sauce which accompanies our fish smacks of Madeira. The *entrées* are conscious of claret and Burgundy. The roasts swim in port, of which the wild fowl are also suggestive. The jellies are mere vehicles of champagne, and gin the creams of curaçoa and the trifle of brandy. Even the preserved fruits at dessert are reminiscent of liqueurs.

Every course is an occasion for double drinking—open intemperance out of a variety of wine glasses, and hidden intemperance off a variety of plates. Verily, it is with cooks that teetotallers must grapple. They are the enemies of sobriety. Why then should they not have their declaration?

Let me suggest that such a declaration should be at once circulated amongst them, and that it should be worded somewhat as follows:—

"As it is believed that the inconsiderate administration of large quantities of alcoholic liquids by cooks, in their professional preparations, has given rise in many instances to dyspepsia and inebriety, the *undersigned*, while unable to abandon the use of alcohol in the treatment of certain dishes, are yet of opinion that no culinary practitioner should introduce alcohol into any composition without a grave sense of responsibility. They believe that alcohol, in whatever form, should be employed with as much care as onions or curry-powder, and that its use in any dish should be accompanied by a caution on the *carte* as to its dangerous properties.

"They are also of opinion that many people immensely exaggerate the value of alcohol as a flavouring ingredient; and since no class of beings hear more of its effects, and possess such power to restrain its abuse, as members of their own profession, they hold that every cook is bound to exert his or her utmost influence to inculcate habits of great moderation in the use of alcoholic liquids by mixing capsicum and other anti-dipsomaniacal agents with their preparations whenever it may be practicable to do so."

Were a document of this kind prepared and signed by the heads of the great culinary corporations, the *chefs* at the Athenæum, Reform, and Wyndham, by a few of the Royal scullions, by cooks holding important public appointments in hotels and eating houses, by the most distinguished consulting cooks, metropolitan and provincial, who lend their professional aid to families in serious emergencies, and by a select number of general private practitioners, it would carry with it immense weight, and do more to restrain intemperance than any number of medical manifestoes.

Commending this subject to the immediate attention of all astute total abstinence agents,

I am, sir, your obedient servant,
A Non-Juring Physician.

Ultima Thule, Feb., 1872.

"MILK."

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—Having often experienced considerable difficulty in procuring milk in anything like a sufficient degree of purity for my patients and their children, I obtained two samples from the Friern Manor Farm Dairy, Charles street, Grosvenor square; one sample denominated "nursery milk" sent by request, and the other obtained from the house of a patient. I was gratified to find that both samples were pure milk, without admixture of any kind, and of a character quite unexceptional in every way, specially the nursery milk, the latter fact I consider of some importance as locality, the method of housing the cattle, and the nature of the food, as largely influence the milk as it does the health of the cows.

. I am, Sir,
Your obedient Servant,
R. Sandon Gutteridge, M.D.

44 Brook street,
Grosvenor square, W.

ON THE INFLUENCE OF ERGOT IN MIDWIFERY PRACTICE.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—Without wishing to take part in the papyromachia of Drs. McKeogh and Sheil, or to attempt any criticism on their relative professional merits, I should like to direct the attention of your readers to the concluding passage of the fourth paragraph of the latter gentleman's letter, which appears in your issue for February 21st, 1872.

The sentence alluded to terminates thus: "The utmost ill effects produced by an ordinary dose, or 'repeated doses,' of ergot is sometimes, not always, a little nausea, or sickness of stomach, which soon passes off; *its power for evil on the fœtus—when the uterus is not excited to action by it—is absolutely nil.*"

Now, I humbly submit that the proposition conveyed in the italicised portion of the foregoing sentence, is one with which few obstetricians will be found to agree, and that it contains assumptions inconsistent with physiological and therapeutical reasoning, and opposed to the experience and teachings of the first masters of the Obstetric art.

Dr. Sheil lays it down that when ergot does not produce uterine contractions, it cannot affect the fœtus. Upon what grounds does he base this statement? Are there not uterine idiosyncrasies which may render that organ insusceptible of the special action of ergot, and in such case will Dr. Sheil undertake to assert that the fœtus would be endowed with a like insensibility? Again, M. Bonjeau, who is, I believe, the best authority on the various properties of ergot has shown that the drug contains two principles, one, ergotine, which produces the special action on the uterus, the other, a colourless fixed oil, "*which alone is the poisonous principle.*" (See M'Namara's "Neligan," 6th edit., p. 284.) Well, every practitioner is aware of the difficulty which exists of preserving ergot; it is a drug most liable to deteriorate, and, as a complex organic principle, such as ergotine, is much more liable to decompose than a fixed oil. One can easily see how a dose of ergot which, if of perfect quality, would strongly stimulate uterine contraction, yet when administered, may be found to produce not this desirable result, but an effect equally undesirable, a distinctly toxic effect on the fœtus, as evidenced by the reduction in the frequency of the pulsations of the fœtal heart.

The foregoing remarks are based on the chemical analysis and physiological action of the drug, as derived from experiments; let us now consider for a moment, the conclusions arrived at by acknowledged masters of Obstetrics, with regard to the action of this drug on the fœtus in utero.

Dr. Hardy, who, as assistant master in the Rotundo Hospital, had ample opportunities of observing the effects of ergot in labour, arrived at the following results, which he published in the *Dublin Journal of Medical Science*, vol. xxvii., p. 224:—

1st. In some cases ergot acts on the uterus in seven minutes after administration, but from ten to fifteen minutes may be stated as the average. In those cases where the children have been born alive the action always commenced within twenty-five minutes, and when a longer period than this elapsed before the uterus took on action, the use of instruments was necessary to perfect delivery, *or the children were dead-born.*

2nd. After the administration of ergot, a marked diminution in the frequency of the mother's pulse was observed in from fifteen minutes to half-an-hour, this diminution being always accompanied by a similar change in the pulsations of the fœtal heart.

3rd. The action on the fœtal heart was observed to be (*a*) diminution in frequency; (*b*) irregularity; (*c*) intermission; while lastly, it became totally inaudible. Dr. Hardy remarks that when the fœtal pulsations have steadily reduced below 110, *and, at the same time with intermissions*, the child will rarely, if ever, be saved. I presume Dr. Hardy used ordinary doses, whether he repeated them I cannot say.

On this point Dr. Beattie remarks that the "administration of ergot to a woman in labour is attended with danger to the child, whenever a time sufficient for the absorption and transmission of its *noxious* properties elapses before the child is born."—It would seem from this extract that Dr. Beattie recognised the existence of a *noxious* influence in ergot apart from its stimulating effects on the muscular fibres of the uterus.—He further adds that "ergot should never be given in any case where there is a likelihood of the labour lasting more than *two hours* after its administration, and when labour is protracted beyond this period, that artificial aid should be resorted to in order to save the child."

I shall not further trespass on your space, Mr. Editor, by quoting from authorities on this subject. I believe the preceding paragraphs are a faithful representation of the teaching of the Dublin School of Midwifery on this particular point, and I feel I should not be justified in occupying your columns to any greater length.

I remain, Sir, very sincerely yours,
J. R. McMahon Murphy, M.B.T.C.D.,
Natural Science Moderator, &c., &c.

February 23rd, 1872.

[This letter was in type and would have appeared in our last, previous to closing the correspondence, but for lack of space. By inserting this communication, it must be distinctly understood that we do not re-open the controversy, nor can we give further space thereto.—Ed. M. P. & C.]

NOTICES TO CORRESPONDENTS.

The Carmichael Prize Essays.—We are favoured by Dr. Edwards Crisp with copy of a letter addressed last week by him to the Medical Council in reference to an adjudication of the Carmichael Prizes of the Royal College of Surgeons in Ireland some years ago. As the question has been very fully dealt with already, we cannot re-open it, except as regards a future competition for the prize.

Ignoramus.—If you will take your share of the personal responsibility by attaching your name to your letter we are ready to give reasons for our selection.

Communications have been received from:—The Military Secretary for India. The Director-General of Her Majesty's Army Medical Department. Dr. Letheby. Dr. Morgan, Dublin. Dr. Drysdale, London. Mr. Hunt, London. Dr. Crichton Browne, Wakefield. Mr. J. C. Dickinson, Chorley. Dr. Bayes, London. Mr. F. B. Courtenay, London. Dr. Donkin, Sunderland. Dr. Michell, Aspatria. Mr. Garrod. Dr. Foster, Bracknell. Dr. Archer, Westminster. Mr. Blaise. Mr. Doulton. Dr. Walker, Chesterfield. Dr. C. Smith, London. Mr. Bellamy, London. Dr. Macnamara, Torquay. Dr. Brooke, Bridgewater. PROFESSIONAL AGENCY AND MEDICAL TRANSFER OFFICE.

50 LINCOLN'S INN FIELDS, W.C.

J. BAXTER LANGLEY LL.D. M.R.C.S., F.L.S.,

&c., (King's Coll.), and Author of VIA MEDICA,

Has always upon his books a large number of desirable investments and available Appointments for negociation.

The business of the Professional Agency is based upon the general principle that no charge is made unless work has been done and services rendered.

No Commission charged to Purchasers.

Full information as to terms, &c., sent free on application.

Office hours, from 11 till 4; Saturdays excepted.

PRACTICES AND PARTNERSHIPS NOW OPEN for negociation (in addition to those advertised in Dr. Langley's List, (which is sent post free on application).

Y 419. LONDON West, DEATH VACANCY. Income upwards of £1,000 a year, of which nearly £700 is received in cash; midwifery £1 1s. and upwards; no horse or conveyance required; the house is held on very advantageous lease; liberal terms would be conceded to a prompt purchaser. The whole connection is believed to be transferable.

Y 418. CATHEDRAL CITY. Average income £510 per annum; good class of patients; population upwards of 30,000; no dispensing; no clubs; no horse or conveyance required; midwifery £1 1s. and upwards. An effective introduction can be given and the highest references.

Y 417. SOUTH EASTERN COUNTIES within a few miles of the coast. The present income is £350 a year but was formerly much greater, and could again be increased to £700; appointments yield £135; there is a convenient residence, with large garden, &c.; no opposition within three miles. The whole connection is transferable; premium £350, of which a part may be paid by instalments.

Y 416. WESTERN COUNTY. In a rich agricultural district, amidst charming scenery, a well established practice realising £500 without appointments; the work is light and fees good; usual midwifery fees £2 2s. The house is vendor's freehold, and could be sold or let. There is capital garden, stabling, &c.; no assistant required; one horse does the work.

Y 415. LONDON suburbs. An old established PRACTICE among an excellent class of patients, realising upwards of £1,000 a year; books have been carefully kept; no cheap midwifery. The house is a convenient modern residence, and can be sold or let, being the vendor's freehold; a partnership introduction would be given if desired; highest references.

Y 412. COUNTRY PRACTICE on easy terms; receipts upwards of £400 a year; patients good class; family residence twelve rooms, large garden, paddock, &c.; rent £30. Complete introduction.

Y 393. Old established COUNTRY PRACTICE in a charming district of the Midland counties, in consequence of the death of vendor's father; receipts between £400 and £500; appointments £85; only one opponent; house contains 9 rooms, with stabling, and at a very low rent; furniture may be taken at a valuation. Premium payable by instalments properly secured.

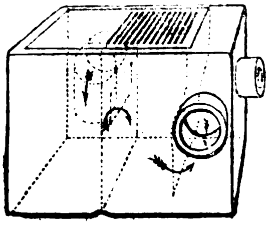
Y 422. In a PLEASANT TOWN in an agricultural district, an excellent family practice, realising on the average of the last three years, £1,047, last year's receipts, £1,234; patients of a very good class; midwifery £1 1s. and upwards; family residence containing fourteen rooms, with stabling, good garden, &c.; easily worked appointments bring in £120 a year; a thoroughly efficient introduction can be given; ill-health the cause of retirement. No gentleman need apply who has not at least £800 at his present command.

Dr. Langley's Quarterly List of selected Practices and Partnerships for January is now ready, post free on application.

SEWER GAS.

As an ABSOLUTE PREVENTIVE of the entry of Sewer Gas into Dwelling Houses by way of the most dangerous inlets—viz., the waste and overflow pipes from cisterns, baths, lavatories, and sinks—DOULTON and CO. strongly recommend the use of

MANSERGH'S IMPROVED GULLY.



By the insertion of this gully in the line of drain outside the house, the common and utterly useless bell-traps may be dispensed with, and direct communication with the sewers is effectually broken.

Price 10s. 6d. each, complete

This is undoubtedly a most important and effective trap for preventing the entrance of Sewer Gases into dwelling houses.—*Lancet.*

MANUFACTURED BY

DOULTON and CO.,

High street, Lambeth, S.E.

Depôts:—

Wood street, Birmingham; Soho street, Liverpool; and Hope street, Salford.

THURLES UNION.

MEDICAL OFFICER WANTED FOR THE LITTLETON DISPENSARY DISTRICT,

Comprising the Electoral Divisions of BALLYMURREEN, LITTLETON, LONGFORDPASS, MOYCARKEY, RAHEALTY, and TWOMILEBORRIS.

NOTICE IS HEREBY GIVEN, that in consequence of the lamented death of Dr. WALSH, the COMMITTEE of MANAGEMENT of the above Dispensary District will, at their meeting to be held at the Dispensary House, Littleton, on Friday, the 22nd ins., proceed to re-elect a duly qualified person to the office of Medical Officer for the above Dispensary District, at a Salary of One Hundred and Twenty Pounds per annum, exclusive of Registration and Vaccination Fees.

Personal attendance of Candidates indispensable.

Applications, with Testimonials, to be addressed to the Honorary Secretary, the Rev. R. F. Lawrence, the Glebe, Littleton, up to 4 o'clock P.M., on Thursday, the 21st MARCH, 1872.

JOHN COOKE, Clerk of the Union.

March 6th, 1872.

CASTLEBAR UNION.

CASTLEBAR DISPENSARY DISTRICT—NORTH DIVISION, No. 2,

Comprising the Electoral Divisions of ADDERGOOLE, BALLYNAGORAGHER, PONTOON, BURREN, and CROAGHMOYLE.

MEDICAL OFFICER WANTED FOR THE ABOVE DIVISION.

NOTICE IS HEREBY GIVEN, that the Committee of Management of the above Dispensary District will, at their Meeting, to be held at the Board room of the Castlebar Workhouse, on Saturday, the 16th MARCH, 1872, at the hour of One o'clock P.M., proceed to the Appointment of a properly qualified Medical Officer for the above Division—(he can reside in the Electoral Division of Ballynagoragher or Addergoole)—at a Salary of One Hundred and Ten Pounds a Year, exclusive of Registration and Vaccination Fees.

Candidates must possess the qualifications set forth in the Orders of the Poor-law Commissioners.

Applications, with Testimonials, to be addressed to the Secretary, JAMES FAULKNER, Esq., Castlebar, up to Four o'clock on Tuesday, the 12th MARCH, 1872. Candidates must be in attendance on the day of Election, 16th MARCH.

(By Order), ROBERT J. NIXON, Clerk of Union.

Board room, Workhouse, 28th February, 1872.

FOR DISPOSAL.—A GENERAL PRACTICE, average income £200 per annum, including Poor-law Union Appointments, which may be secured to an active, steady, and gentlemanly man, who would be able materially to increase the present income. For particulars and terms, apply fully to X. Y. Z., at the office of the MEDICAL PRESS AND CIRCULAR, 20 King William street, Strand, London, W.C.

CLONES UNION.

THE BOARD OF GUARDIANS OF THE ABOVE Union will, at their Meeting, to be held on Thursday, the 14th inst., consider tenders for supplying the Workhouse and Three Dispensaries, up to 25th MARCH, 1873, with MEDICINES and MEDICAL APPLIANCES of the best quality, to be delivered free of carriage or any additional charge whatever. The invoices of supplies to be numbered and furnished in duplicate, and to set forth only the prices of the goods ordered.

No entry of charge for any article used in packing or conveying the medicines, will be allowed in the invoices. The Contractor to take back such articles at his own risk and cost.

Forms of tenders will be forwarded on application to me.

(By Order), ALEXANDER BAILEY, Clerk of Union.

Board Room, 1st March, 1872.

OUGHTERARD UNION.
CLONBAR DISPENSARY DISTRICT.

THE COMMITTEE OF MANAGEMENT OF THE Clonbar Dispensary District will, on Tuesday, MARCH 26th, at the hour of Eleven o'clock in the forenoon, at the Dispensary, Clonbar, elect a Medical Officer for (No. 1) District, in room of Dr. McGuire, resigned. Salary, One Hundred Pounds per annum, exclusive of Vaccination and Registration Fees.

Testimonials and qualifications to be sent to

MARTIN BERNARD JOZER, Hon. Sec.

Russina, Clonbar, Co. Galway.

PRELIMINARY EXAMINATIONS of the COLLEGE OF SURGEONS, MR. J. ERLE BENHAM, (formerly of King's College, London, Author of the Student's Guide), whose pupils have always met with very great success, has commenced to take his CLASSES, and to give PRIVATE INSTRUCTION for the next JUNE Examination. For particulars and syllabus of Testimonials, address to 20 Devereux Court, Temple, or to the care of Messrs. Butterworth, 7 Fleet street, London, Her Majesty's Law Publishers.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.—DR. QUAIN will lecture on March 15th, 20th, and 22nd, at 5 p.m., "On DISEASES OF THE MUSCULAR WALLS OF THE HEART." Members of the Profession will be admitted on presentation of their cards.

By order.

ASSOCIATION OF CERTIFYING MEDICAL OFFICERS of GREAT BRITAIN and IRELAND.—Gentlemen holding the Appointment of Certifying Surgeons under the Factory Act, who may not have received a copy of the last Report or who may be desirous of joining the Association, are requested to communicate with the Hon. Secretary, Mr. Stansfeld, Redland, Bristol, who will be glad to send a copy of the Report and to give every information respecting the objects of this Society.

Annual subscription Five Shillings, payable to the Treasurer, Dr. Waters, Bishop street, Coventry.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.

FIRST or PRIMARY PROFESSIONAL EXAMINATION for the LICENCE.—The next Examination will commence on Monday April 1st. Students are admitted to this Examination after the termination of the Second Winter Session of Professional Study at a recognised Medical School.

SECOND or PASS EXAMINATION for the LICENCE.—The next Examination will commence on Monday, April 8th. Gentlemen who have completed four years of Professional Study according to the College regulations are eligible for admission to this Examination.

Registered Medical Practitioners, qualified before January, 1861, are admitted to examination under special by-law.

Candidates are required to give fourteen days' notice in writing to the Registrar of the College, with whom all certificates and testimonials required by the by-laws are to be left at the same time.

Pall-mall East, 1872. H. A. PITMAN, M.D. Registrar.

The Medical Press and Circular
OFFERS UNUSUAL ADVANTAGES

FOR the Insertion of announcements, from its extensive and largely increasing circulation in each of the three divisions of the United Kingdom and the Colonies. Being also supplied to the Hospital Libraries, &c., it will be found a most valuable medium for Advertisements of Books, Vacancies and Appointments, Sales and Transfers of Practices, Surgical Instruments, Chemicals, and Trades generally.

The scale of charges is as follows:—

Seven lines and under	£0	4	0
Per line afterwards	0	0	6
One quarter page	1	5	0
Half-page	2	10	0
One do.	5	0	0

When advertisements are given for a series of insertions, a very considerable reduction from the above scale is made.

☞ Advertisements for Insertion in this Journal must be at the OFFICE, on SATURDAY, by Two o'Clock.

The Medical Press & Circular.

"SALUS POPULI SUPREMA LEX."

CLINICAL NOTES AND OBSERVATIONS.

By Henry Lee,

Surgeon to St. George's Hospital.

No. IV.—Cases of Severe and Protracted Constipation depending upon Peritonitis.

J. P., æt. 47, was sent into St. George's Hospital on the 1st of November, 1871, with a report that he had passed nothing by the intestines for three weeks. The abdomen was enormously distended and tympanitic.

The skin covering it was marked with a large number of pustules, the result of the application of croton oil. The distension of the stomach commenced about eight weeks previous to his admission, but for eight months the bowels had been very much constipated, and he had vomited occasionally. He had lost flesh, and had been accustomed to drink.

The urine contained small quantities of albumen, lithates, blood, bile, and epithelial scales, sp. gr. 10·24.

The face was covered with spots of acne, the tongue was coated, and he complained of great dryness of the mouth and fauces.

The rectum was carefully examined, but no evidence of obstruction could there be found. There was, however, fulness and dulness on percussion in the left iliac region.

He was ordered a grain of opium every six hours.

Two days after his admission an enema was carefully administered. Three pints were injected, and on the next day a long flexible tube was passed for about twelve inches. Two pints of gruel were injected through this, and a large quantity of fœtid matter was now for the first time passed; all purgatives, of which he had taken a large quantity, having failed for three weeks to produce any effect.

Nov. 7.—Pulse, 120; appetite good. Had had a natural motion.

Nov. 13.—Had a very troublesome cough.

Nov. 14.—The bowels acted several times. Fluctuation could now be detected in the abdomen. The anterior part, as he lay upon his back, was still tympanitic, but the sides towards the back were dull on percussion.

Nov. 18.—Feet, ancles, and scrotum œdematous.

During the month of December he lost flesh, complained of much pain round the upper part of the stomach, and was troubled with cough.

He died on the 13th of January.

On a *post-mortem* examination the lungs were found congested, and contained some miliary tubercles. The peritoneum was thick and opaque from old inflammation. The stomach for the space of five or six square inches was firmly bound to the lower surface of the liver by old adhesions. The capsule of the liver was thickened; its substance cirrhosed and fatty. There was no obstruction in the intestinal canal.

In a second case, I met some years ago Mr. Tatum, of Salisbury, in consultation. A gentleman while out shooting was seized with a violent shivering fit. This was followed by most obstinate constipation and swelling of the abdomen. A London physician of eminence who had seen the case had, I was informed, given it as his opinion that there was organic disease of some portion of the large intestine, and an operation was contemplated. After some three weeks without any passage through the bowels the patient died. A large quantity of fluid was found in the peritoneal cavity, but there was no disease or obstruction to any part of the intestinal canal.

In both these cases an operation was seriously contemplated; indeed, the first was sent into the hospital with that view.

LECTURES ON DERMATOLOGY.

Delivered in the Royal College of Surgeons of England, in February, 1872, by

ERASMUS WILSON, F.R.S.,
Professor of Dermatology to the Royal College of Surgeons of England.

Furunculous Affections.

IF I were to say that all the inflammatory affections of the skin take their origin in the follicles, I should undoubtedly be saying more than is perfectly warranted by the phenomena of cutaneous disease; but if I were to affirm that in every inflammation of the skin, congestion of the follicles plays a conspicuous part, I should be fully borne out by the illustrations that have come before us up to this time and prospectively, by nearly the whole of the remainder of the series. The follicle, in its early development, is a growth inward of the surface of the cutaneous layer of the embryo; but, from its inward position it occasions a change, and somewhat of a concentration of the normal cutaneous functions. While the visible surface of the skin is divided in its duties between sensation and secretion, the follicle is given up wholly to secretion, and at the same time assumes the prerogative of an internal and a glandular organ. From this circumstance it derives, on the one hand, a certain isolation which enables it to perform an independent part, and, on the other, from the possession of a more acute sensibility of organisation, is apt to become influenced by morbid conditions of the general system which are unfelt by the rest of the skin. It is in some such manner as this that we must endeavour to explain those highly wrought operations of inflammation which we meet with in the next of the groups which comes under our consideration, namely, the pustulous and furunculous affections of the skin. In these affections the principal morbid characters are—a degree of isolation referable to the follicular origin of the disease; a deeper implantation within the skin; a more advanced development in the nature of the inflammatory product, namely, pyogenesis, and beyond this a tendency to gangrene, and sometimes to ulceration.

The ancient dermatologists made a distinction of pustules into the cold and the hot, the former they named psydracium, the latter phlyzacium. The former, in fact, are simple vesicles produced on the surface of the skin, and deriving their purulent contents from the cells of the rete-mucosum; we have already had examples of psydracia or cold, that is to say, non-inflammatory pustules before us in impetigo, which is sometimes an eczema of considerable intensity, and sometimes the mere effect of the eczematous inflammation operating on a feeble constitution. Such pustules are simply vesicles distended with a purulent fluid, and when they dry up and fall off, they leave behind them no mark on the skin, no trace of their previous existence.

The hot pustule or phlyzacium on the other hand is always more deeply seated, originating in the walls of a follicle, sinking deeply into the corium, and deriving its pus from the connective and other tissues of the substance of the skin. Hence, it is slower in its progress, more permanent, and more lasting; and when its scab falls off in a longer or shorter time, it leaves behind it a pit and a cicatrix of lasting endurance.

The phlyzacium is the true pustule of the skin, and we term it *ecthyma*; and ecthymata are frequently found in association with furunculi, thus establishing a relationship between them, and leading up to the little boil which is so commonly met with on the eyelid, namely, *hordeolum*; and that larger and multiple boil which has received the name of *anthrax* from the Greeks, and *carbuncle* from the Latins. Moreover, it is in this group, although unfortunately, not as yet in our collection, that we meet with a remarkable form of septic pustule named pustula maligna and certain exotic boils of much interest, for example, the Aleppo pustule or boil, the Delhi boil, the Scinde boil, and so on.

Turning to the catalogue for an illustration of the only example of furunculous affections that we have before us, namely, the pustulous affection ecthyma, we find a water-colour study of ecthyma, illustrating colour and form of the pustules and their several stages—incipient, mature, encrusted, ulcerative, and cicatricial stains. This drawing was made from a case of some interest in a surgical point of view, which pretty well illustrates the nature of the affection and its cause. A man had broken his leg, and the leg had been confined in splints and bandages for several weeks. He experienced considerable irritation from the presence of the bandages, and when they were removed, the limb was found dotted over with ecthymatous pustules. They are apt, not unfrequently to occur in the neighbourhood of boils, particularly where the tissues of the skin have been lowered in vitality by the prolonged use of a poultice or water dressing; and they are met with occasionally without apparent cause, namely, as an idiopathic affection.

Like other diseases of the skin, ecthyma is variously modified by the state of constitution and age of the patient. When the eruption has broken out suddenly it has been named ecythma *acutum*; but when, as is more commonly the case, its outbreak and course are tediously prolonged for weeks and even months, it merits the designation of chronic—ecthyma *chronicum*. Ecthyma is essentially a disease of debility, of a low state of tone of the system; and, where the constitution has been depressed by debilitating causes, determining a state of cachexia, it has received other names which convey the idea of the nature of its existing state, for example, ecthyma *luridum*, *cachecticum*, and *gangrænosum*. A form of the eruption met with in ill-fed and ill-tended children has also been named, ecthyma *infantile*; and in Ireland a similar affection has received the designation of " burnt holes,"

Surgical diseases require less variation of treatment than medical diseases, and a similar principle of treatment is applicable to every kind. The modifications, where such may be required, are demanded less by the variety or special peculiarities of the disease than by that of the constitution and habits of life of the patient. It is a rule without exception that we must endeavour to regulate digestion and elimination, and at the same time or immediately after, do all in our power to restore the healthy tone and vigour of the organism. It seems a mere truism to say that a part will more readily recover its health when allied with a healthy whole than it will when the latter is unsound, but it is a truism that should be borne always in mind and steadily acted upon in relation with every local disease. Another not less important rule of treatment is to remove or remedy the cause of the disease. The local treatment again differs from the constitutional treatment less in the principle involved than in the terms which we employ to give expression to it. For example we must *palliate* and then we must *stimulate* and give tone. By palliation alone many an eruption may be cured; and a considerable proportion of the remainder will give way to a well regulated stimulation.

In the instance of ecthyma, after a tonic aperient, every kind of tonic may be called into requisition, whether dietetic, or digestive, or stimulant. Nitro-muriatic acid, with a bitter such as tincture of gentian, will do us good service in one case, and not less will citrate of iron and quinine in others, and among children the phosphates of iron and lime and cod-liver oil. While, locally, we shall derive our best help from the lime water and oxide of zinc lotion, and the benzoated ointment of oxide of zinc. Where ulceration is established the unguentum resinæ will be required, or solutions of carbolic acid, nitrate of silver, or chloride of zinc.

In the treatment of boils we have to consider their period of growth. At first our remedies should be ectrotic; secondly, failing to arrest the progress of the inflammation, and directing our measures to the relief of the pain accompanying the pyogenic stage, we encourage suppuration; and, lastly, we resort to stimulant means to aid in the separation of the slough and the healing of the ulcer. Our ectrotic remedies suitable to the first indication are: the galbanum and opium plaster spread on wash-leather; pencilling with liquor plumbi; and pencilling with tincture of iodine. The treatment of the suppurative stage is accomplished by a poultice; and that of the healing stage by the old basilicon ointment, the unguentum resinæ of our modern pharmacopœia. Nevertheless, other methods of treatment have their claimants for preference, for example, early incision, and, in the second stage, the application of potassa fusa.

The anthrax or carbuncle, or monster boil, is treated on a principle similar to that of the furunculus; and surgeons are divided in opinion between external support and pressure by means of a plaster; the early use of the knife; and the application of the poultice. Perhaps it may happen that some cases will run their course most favourably by support alone, while others are brought to a successful issue more speedily by the knife, and others of a painful character can only be relieved by the regular succession of hot and ample poultices. Likewise in the detail of operation by the knife, some may prefer a single incision, others a crucial incision, and others, again, subcutaneous incision.

Traumatic Affections.

We have now passed in review four important groups of cutaneous affections taking their origin in common inflammation: the first of those groups is represented by *eczema;* the second, by *erythema;* the third, by *pemphigus;* and the fourth, by *furunculus;* there remain, however, certain inflammatory affections which take their origin in *traumatic* causes, such as wounds, bites, stings, mechanical and chemical irritants, &c., and these I have grouped together under the head of traumatic affections.

It may, very reasonably, be inferred that this is a group into which may be drawn an extensive and interesting variety of illustrations; but at present we have in our collection only three examples of the class—namely, the ulcer met with in artisans engaged in arsenical manufactures; the coal tar or aniline pigments, which are known to give rise to inflammation of the skin; and affection of lymph vessels and glands, occasioned by propagated irritation consequent upon inflammation of the integument.

Arsenic, when taken internally in large does, or for a considerable period of time, is apt to give rise to erythema of the skin or dermatitis; and it not only affects the skin, but also certain of the mucous membranes, for example, the conjunctiva, and mucous membrane of the nostrils and pulmonary passages. Inflammation of the conjunctiva has become the ordinary test of the saturation of the system by arsenic; just as redness of the free edges of the gums indicates saturation by mercury, and blueness of the same part saturation by lead.

Inflammation of the mucous membrane of the nares is sometimes accompanied with ulceration and perforation of the septum, and inflammation of the bronchial membrane very commonly, with a dry and irritable cough.

On the general surface of the skin, besides dermatitis, arsenic is apt to give rise to discolouration from excessive pigmentation and not infrequently to desquamation. While on the palm of the hands and sole of the feet it produces not only desquamation, but also thickening of the epidermis to a considerable degree from hyper-nutrition, and occasions the formation of minute granular corns, each little corn corresponding with the aperture of a sudoriferous duct.

In certain manufactures in which arsenic is largely used, as in the production of pigments of a green colour, it would appear also that ulcers are not an uncommon phenomenon. The model No. 129 exhibits ulcers of the wrist, fingers and thumb, produced by the irritative action of arsenic on the skin. The ulcers have the same general characters, they are deep, coated on the surface by a buff-coloured gelatinous looking lymph, bordered by a dark red margin, and surrounded by a purplish-red, thickened, and desquamating areola. The ulcers on two of the fingers occupy the side of the first phalanx near its base, and are larger than the rest, possibly from the facility of lodgment of the poison in the inter-digital grooves, one of the two ulcers being formed by the confluence of three sores of smaller size. On another finger the ulcer is smaller and situated at the side of the middle phalanx, while on the thumb the ulcer is seated immediately beneath the free extremity of the nail, and is partly covered with a black crust.

The patient was a man, æt. 55, of good constitution and good family history. In July 1865, he took service in a factory of chemical products, and was employed in preparing an arsenical colour, the Schweinfurt green. After a month or six weeks he was attacked with catarrh and coryza, and was troubled with ulcers on the scrotum, sides of the fingers, and wrists. He was admitted into Bazin's wards, and was discharged cured at the end of forty days. In November he returned to his duties in the factory, and at the end of a month, had a recurrence of his previous symptoms, namely, catarrh and coryza, which gave a nasal intonation to his voice, ulcers on the inner side of his thighs, on his fingers and wrists, and ulcerating papulæ on his cheeks near the angle of the mouth. At the end of the month of March, he was re-admitted into hospital under the care of Lailler; at this time he was debilitated, his appetite was good, and his bowels were regular. There were ulcers on the inner side of the thighs and legs, on the scrotum, on the hands, wrists and forearms, between the toes, on the cheeks, and within the nostrils, the septum nasi being perforated, and the lining membrane red and swollen. There was a mucous discharge from the nose, but no affection of the mucous membrane of the mouth and fauces. At this period the disease had been three months in progress, but there were no indications present of constitutional symptoms occasioned by the arsenic, and at the end of a month he was discharged nearly cured, the treatment in the interval being of the most simple description, namely, warm baths, with aromatic wine, styrax ointment, and nitrate of silver; the essential treatment, in fact, being, abstraction of the cause.

Of a nature allied with arsenic, and according to some chemists, as a consequence of the presence of arsenic itself, the aniline dyes have the property of exciting inflammation of the skin, Their effects have been observed both in the hands and in the feet, from the use of gloves and stockings coloured with those pigments. The feet, however, have been most frequently the victims, and the dyes in some instances have been transferred to the skin, while in others, the pattern of the stocking has been found represented on the skin, by tracings and figures of inflammatory hyperæmia. The dermatitis occasioned by the coal-tar pigments is frequently set up in the course of a few hours; it presents the characters of an aggravated eczema, and is attended with considerable effusion beneath the epidermis, which it raises up into large blebs, sometimes occupying the whole surface of the sole of the foot.

A gentleman who had worn a pair of new socks of a crimson aniline colour for a few hours, suffered so much pain in his feet, that he was unable to walk for a short distance to his home; the pain was stinging and prickling, indicative of a special irritation of the nerves of the skin; the feet became swollen; they were red and hot, and covered with a papular and vesicular rash, the latter in a few places increasing to the extent of blebs of considerable dimensions.

Not unfrequently the inflammatory rash is transferred to the hands, even when those members have not been in contact with the poison, and a general irritation of the entire skin is sometimes set up by the process, which once was called sympathy, but is recognised now, as propagated irritation. The progress of the dermatitis is always slow, and the inflammatory irritation liable to recurrence at intervals of a few weeks for a considerable period of time, sometimes for several months, and in a few instances for years. This phenomenon is not without its parallel in some other affections of the skin, particularly in eczema, and is also met with in instances of dermatitis, occasioned by other irritant poisons.

A manufacturer writing to me on the subject of an "aniline orange dye," an acid pigment, which is so volatile as to stain paper brought in contact with the fabrics dyed by its means, and which would affect in a similar manner the human skin, observes:—Several workmen have suffered severely from wetting their hands with this solution, even when the contact has lasted merely for a few minutes; the effects being an eruption of the skin, not only of the hands, but, in one case, of the whole of the arms, ears, and feet. The affected skin was covered with pustules, which became confluent; and when the eruption had apparently subsided, it returned again and again; two or three months elapsing before the effects finally disappeared.

A similar kind of eruption is sometimes occasioned by solutions of bichromate of potash; as, also, by certain poisonous shrubs, such as the rhus toxicodendron, or poison-oak of America, and the deadly night-shade, probably the atropa belladonna of the same country.

In our collection, this subject is not represented as I could have wished, either by drawings or models, but simply by two socks, Nos. 130 and 131. The former is a silk sock of a bright scarlet colour, probably dyed with the "coralline" pigment. A pair of these socks, worn for a day, gave rise to an intense inflammation of the feet, *dermatitis anilina*, which lasted for a fortnight, and was repeated at intervals of a few weeks for many months. The general features of the inflammation were—heat, swelling, itching, tingling, and large blisters, while an eczematous irritation was propagated, more or less extensively, to the whole body of the patient, especially to the hands.

No. 131 is another sock of a mixed fabric, the colour being in a measure lost by washing; the socks were originally striped with purple, and the impression of the purple stripes was made visible on the legs of the patient in the form of dark red bands that resembled burns. As in the preceding instance, the *dermatitis anilina* was severe and recurrent and repeated for many months, and at its height gave rise to swelling of the inguinal glands.

The remaining example of traumatic affection is an instance of inflammation of the lymphatic vessels, or lymphadenitis of the arm. The model No. 132 exhibits a blotch of eruption on the metacarpus of the thumb and first metacarpal space, and a line of inflamed tubercles (*adenomata*) extending from this blotch upwards to the axilla. The blotch of cutaneous disease is partly covered by a thin squamous crust and partly denuded, and the tubercles are ten in number. The tubercle nearest the inflamed blotch is in a state of ulceration, as also are the second and the third. The fourth has the appearance of containing pus, and is reaching maturity; the next three tubercles have the dull purplish hue of decline, and are squamous at the summit, while the three remaining are in a progressive stage. In the intervals of the tubercles, particularly on the upper arm, may also be seen a pale ridge indicating a line of deep-seated inflammation and thickening following the course of the lymphatic vessels. A glance at the model is sufficient to show the progress and effects of an inflammation of the absorbents. This disease is termed by Bazin "hydrose adenite traumatique," indicating the presence of tumours of adenoid tissue, or *adenomata*, in the course of lymphatic vessels.

The history of the case has unfortunately been omitted, and we are left to the conclusion that the inflammation of the lymphatic vessels was the consequence of the eczematous inflammation of the integument of the hand.

EXCISION OF THE HIP-JOINT, WITH SOME PREFATORY OBSERVATIONS ON THE OPERATION.

By J. K. Barton, F.R.C.S.I.

History of the Operation.—Originally *proposed* by Charles White, of Manchester, in 1768, who when describing an excision of the head of the humerus performed by him, stated that he had upon the dead subject practised the same excision upon the femur at the hip, and said "cutting through the bursal ligament and bringing the knee inwards, the upper head of the os femoris hath been found out of its socket, and easily sawn off; I have no doubt that this operation might be performed upon a living subject with great prospect of success."

Disputed for many years, it was for the first time *performed* by Antony White, of the Westminster Hospital, London, in 1822. The patient, a boy, 9 years of age, was the subject of advanced disease of the hip; abscess; sinuses; dislocation of the upper end of the femur with dorsum ilii; and was in a very debilitated state. "The bone was divided with a small straight saw, about two inches below the top of the great trochanter, raised with a spatula, and then carefully detached from the ilium. The knee which had been long immovably embedded in the opposite thigh, was now with facility brought into a straight line, and the whole limb was secured with a long splint, and treated as a compound fracture." The result was most successful. "Within twelve months a most useful compensation for the loss of the original joint was obtained, perfect flexion and extension, and every other motion, except the power of turning the knee outwards, were restored, but the femur did not grow after the operation."

In 1828, Mr. Hewson, of Dublin, performed the operation unsuccessfully, the patient dying three months after the operation, with large purulent collections extending into the pelvis through an opening in the acetabulum. The operation was performed for the first time for fracture from gunshot wounds, by Oppenheim, of Hamburgh, in 1829. Sir B. Brodie performed excision for disease in 1836, and in 1845. The brilliant operations and writings of Sir William Fergusson, gave a great impetus to the operation in England. In the Crimean war it was performed six times by British surgeons for gunshot injuries; one case only successful.

In the late American war, excision of the hip was performed in sixty-three well-authenticated instances, which form the basis of an admirable report upon the subject by Assistant-surgeon Otis, of the United States Army.

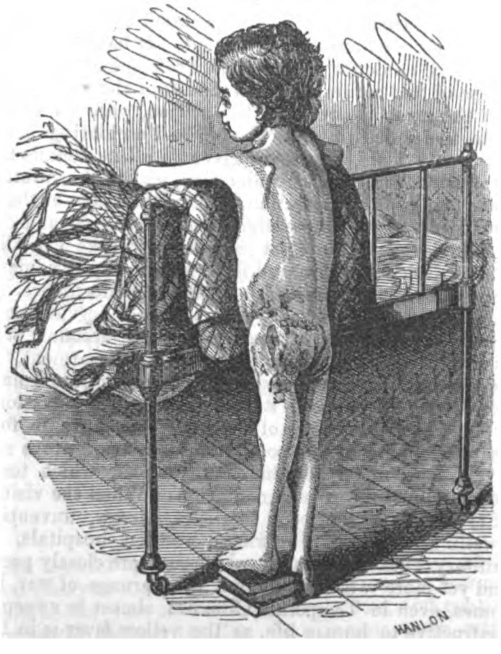
In American civil hospitals, it has become not only a recognised, but I may say a favourite operation, both in the Belle-vue Hospital, New York, where Dr. Sayer has operated, and at Boston.

In Dublin, since the unsuccessful operation of Hewson, in 1828, there does not seem to have been any repetition of excision of the hip, until the late Mr. Collis, at the Meath Hospital, about eight or ten years ago performed the operation upon a lad apparently about sixteen years of age. (I have not seen any report of this case, but having been present at the time, I state from memory what appeared to be the age of the patient.) This case proved fatal, and as far as I am aware, the operation has not been repeated until last summer, when I operated upon the child, whose case I am about to relate. I may be incorrect in my conclusion, that mine is the first successful case of excision of the hip in this city. I have not been able to find the record of any case operated upon successfully or unsuccessfully except those I have mentioned, but if any member can correct me upon this point, I will most willingly waive my claim inasmuch as it seems but little to our credit that the advantages gained elsewhere by excision of the hip had not been sooner realised here.

Hip Disease—Excision.

Jabez Elliot, 6 years of age, a remarkably pallid little boy, born in America, was admitted to the Adelaide Hospital, upon the 17th February, 1871, suffering from well-marked symptoms of disease of the left hip joint. Upon examining him in the out-patients' room before he was brought up to the ward, I found the left thigh considerably flexed on the pelvis, and so exceedingly painful was the slightest motion, that any further examination had to be postponed. When examined in bed next day, a considerable fulness was observed behind and above the trochanter, so that taking the acute pain and constitutional disturbance, which was considerable, into account, I had no hesitation in saying that suppuration had already taken place, in fact that the case had entered upon the second stage of disease of the hip joint.

The only history which could be obtained of this case, was that about fourteen months before the time of his admission, he had fallen down a high flight of stairs, and that from that time he was observed to be lame, that previous to the fall he was a healthy lad, that two brothers had died at an early age. The painful starting of the limb was at once relieved by the pulley and weight (3lbs.) was found to give permanent relief to this distressing symptom, and consequently he began at once to sleep soundly at night, which he had not done for some time. His countenance very soon lost the expression of pain and fear of pain which he had at the time of admission, and the child's appetite began to improve. As proof of the relief afforded by the weight, I may mention that when it was removed to make some necessary change in its mode of application, the little patient earnestly asked for it again, and frequently when asked would he like it taken off, he begged to have it left on. For about a month after admission all the signs of suppuration abated, so much so, that it appeared as if I had been premature in saying suppuration had already begun. Not long after this time, however, fluctuation was discovered a little above and behind the trochanter, and when opened a quantity of strumous pus was evacuated, and a sinus leading down towards the head of the bone was left. Subsequently other openings were made, all apparently communicating with the posterior part of the joint. The treatment both local and general was that which I find in the great majority of cases successful in bringing about a sound anchylosis, viz., the patient was placed on a perfectly level hair mattress, the limb was steadied and kept at rest, and in a perfectly straight position by "the weight," a poultice was kept round the hip while the abscess was forming, afterwards the openings were daily syringed with a solution of chloride of lime and lint soaked with the same kept on them. Cod liver oil, syr. iodidi ferri or phosphatis ferri were given internally, and an egg and milk diet perseveringly given. This boy's health which at first improved after the treatment commenced, subsequently gave way before the constant discharge from the diseased joint. Diarrhœa, which was very difficult to check threatened to carry him off, and it became evident that the ordinary modes of treatment would, in this case, prove insufficient, and that the case hreatened to end fatally. My colleagues agreeing with me in this view of the case, I determined with their appro-ation to excise the head, neck, and trochanter of the emur, and whatever of the diseased innominatum it was ossible to remove by the gouge. The operation was erformed upon the 28th of June, just four months after is admission to hospital, and about eighteen since the ll which preceded the commencement of the disease. he operation was performed as follows:—The little tient having been brought fully under the influence chloroform, he was turned slightly over on his right le, so as to present the diseased hip freely to view. A mi-lunar incision was then made, about six inches in ngth, commencing about two inches above the prominence formed by the trochanter, extending downwards d backwards, and then curving forwards and still downwards, until it ended about two inches below the same prominence, the diseased bone was thus immediately reached, the ligaments were quite destroyed, so that abduction of the limb at once turned out the head of the bone, or rather what remained of the head, out of the widened acetabulum. But little was required to free the bone, as the saw was applied below the trochanters. The bone when cut looked not only very vascular, but soft, so that another slice about an inch in thickness was removed, the acetabulum was now examined, and felt to be rough and very much widened out, all its cartilage having been absorbed. The gouge was used wherever the bone felt carious, and a good deal of softened bone was scraped away. Torsion stopped the bleeding of a few little arteries. No ligature was required, the whole wound was then washed with a strong solution (1 to 12) of carbolic acid, which checked oozing and then small pledgets of lint were soaked in a weaker solution (1 to 30) and packed into the cavity, the extremities only of the curved incision being closed by suture, the middle was left open, the whole was covered with layers of lint soaked in carbolic oil, gutta percha over all. The boy recovered well from the chloroform, and was soon safely removed to bed. When there the means employed to keep the limb steady in the straight position was simply one long splint, placed upon the *inside* of the limb, against which the foot rested, the splint being firmly secured to the foot rail of the bed, and in addition to this, to prevent starting a light weight was suspended to the foot in the way he had been so long familiar with, these two fulfilled the indications perfectly, viz., to prevent starting of the muscles to keep the limb extended, and to prevent rotation. The progress of the case was very satisfactory, the boy's condition within a fortnight was manifestly so much improved, that it was remarked by all about him. The wound healed at once at the extremities, the middle was kept freely open, the cavity, which reached down to the diseased acetabulum, being sponged out daily with a weak solution of chloride of lime, and then filled with charpie. The boy's state at present, more than six months having elapsed since the operation, is as follows:—In the centre of the line of incision, which is otherwise soundly healed, there is an ulcerated spot about the size of the nail of the index finger, through which the probe passes readily into the diseased acetabulum. A *few drops* (not more) of purulent matter is discharged



upon the dressing from this orifice. The excised hip measured from the anterior superior spine of the ileum to the coccyx, is two inches larger than the sound one, and when viewed from behind, the cause of this increase in size is seen to be twofold. 1st. The muscles of the sound limb are much wasted from long disease, while the hip which has been operated upon is rendered round and bulky by the fibrous effusion which has been copiously thrown out connecting the cut end of the femur to the os innominatum. The leg measures only 1¼ inches less in length than the other. The boy has no pain whatever in the limb. He can sit for hours either in his bed or in a chair without any uneasiness, and when supported upon crutches, can place the limb firmly down and put his weight upon it without any feeling of pain. When lying on his back he can flex and extend the leg at the knee with ease and agility, and can raise the whole limb off the bed, the pelvis moving with the femur. His appetite is good, and his strength is steadily increasing.

INFLAMMATORY FEVER AND TYPHUS FEVERS.

By Wm. Brett, L.R.C.P. Edin., M.R.C.S. Eng.

The long illness of the Prince of Wales, and his happy yet slow Progress to Convalescence after a protracted struggle have led the public mind to the consideration of fevers generally, and to that of typhus fever particularly. The extraordinary duration of the disease, the rank of the patient, and the infrequency of typhus in the higher circles have annexed to the case of the Prince a remarkable character, so remarkable indeed, and standing out so distinct and apart from ordinary cases, that it seems to demand a strict *annotation* illustrated by a public record of its precise nature, and treatment. It has often occurred to me, as, no doubt, it has to the Profession generally, that a case of this nature in which the life of the *heir-apparent*, and the great interests of the nation, were for so long a time suspended in the balance, and oscillating between hopes and fears, should be given in all its details to the Profession for their consideration, and to the public for their safety, and satisfaction. The publication of the case would add to our knowledge of vital *statistics*, and do incalculable good. In 1854 cholera raged, like a pestilence around Golden Square, and filled many a happy home with bereavement and lamentations after its subsidence. The chief physician, who had rendered signal services on that occasion, published a most interesting account of the disease in all its relations to causes and treatment. The Suggestion I have ventured to offer, has therefore a medical precedent to support it. Moreover, the invasions of typhus fever, like those of cholera, which have, in former years, decimated whole populations may again prove extensively fatal under certain circumstances, which tend to generate, and propagate contagion. When the visitation of typhus falls upon poor localities, narrow, unventilated dwellings, swampy districts, crowded hospitals, large military encampments, in which men are closely packed; and yet more when it follows the carnage of war, it becomes, even in Temperate Climates, almost as sweepingly destructive to human life, as the yellow fever is in India. These facts duly considered deserve ventilation in the press, and seem to suggest to the skilful physicians who successfully conducted the Prince's Case, the noble work of publishing it with all its symptoms, circumstances, and treatment. Such a work, the whole body of the profession would receive as a new light to science, 16,000 or 20,000 Medical men (many of them of co-ordinate rank, and equal ability with their brethren who attended the Prince of Wales) would study it, examine it, compare it with their own experience, and be enabled to determine, yet more accurately, the true nature and treatment of fevers inflammatory and typhoid; respecting which medical Teachers, and Celebrities, have so widely differed. In the last few years these differences have increased. A new medical school has arisen to extinguish the Old Medical School, just as young England laboured but fainted in its work to put out our Old England.

Nature is ever the same in all her instincts, ways and works. Therefore it is not too much to expect, that the wise sons of Æsculapius would discover her secrets (her healthy and diseased springs of life), and treat the sorrows and sufferings of so kind and demonstrative a mother according to a *rational*, *consistent*, and safe principle of cure. I am sure from much observation, and an experience of 40 years or more, that if the real nature of disease, and a sure settled principle of treatment were only discovered (and a free, generous intercommunication between the few and the many, as now suggested, is the best mode of discovering it), disease, sufferings, and death, would diminish considerably; and the bed of sickness would be stript of half its terrors. It is, therefore, a matter of immense importance to our national, social, and moral life to discover and observe True Principles in relation to fevers generally and to typhus particularly; because typhus fever (which is called, according to the places of its attack), gaol-fever, ship-fever, camp-fever, &c., destroys human life not in *a numerical proportion, but in a sort of geometrical proportion*, so that if a single family of *five persons seized by it produce a given ratio of pestilence*, ten or fifteen persons labouring under *typhus fever* will produce one hundred times or one hundred and fifty times as much.

The Cause of this Startling Disparity is still a secret. Therefore every possible effort should be made to settle the nature of fevers and their treatment. The almost helpless state of the Prince for some time imparts a deep interest to this subject; and truly it is to be regretted, that while nature spreads out facts and truths and their most striking manifestations on the human body, so as almost to speak them, physiologists and Medical Sages (less wise because more irascible than Hippocrates, Galen, or Celsus), loudly differ *toto cælo*. The late Drs. Armstrong and Elliotson treated inflammations and fevers which they pronounced inflammations, with the lancet and mercury boldly. Dr. Armstrong was so absolute on this point that he called bleeding the right arm and mercury the left arm of medicine. Dr. Armstrong employed the lancet bravely even in typhus fever. Alas, poor human nature! Clever men are prone to extremes; so other men, their successors, rush into the opposite course; and thus it is, that good principles, and good treatment, are brought into disrepute by abuse. The late Dr. Todd prescribed stimulants, wine and brandy, in fevers, and inflammations. Great evils, as all intelligent medical men know, have flown from both extremes. "*In medio tutissimus ibis*," is a good MAXIM: and the Profession, always alive to the public interest and to their reputation, have judiciously circumscribed Todd's mischievous hobby. It has happened to me, as it has to many medical practitioners, to be consulted in extreme cases of gastritis (inflammation of the stomach), with death at the door; simply because stimulants, wine and brandy, were administered under the erroneous opinion that the patient was sinking. There was indeed a rapid and a fatal sinking, not by the disease, but by the brandy. Many die in this way amidst horrible sufferings from the united irritations of disease and stimuli, simply because the state of the patient, is *guessed at* and *not truly discerned*. There are sure signs that infallibly guide the skilful observer. What are they? Why: In *gastritis*, or any other inflammation; when high fever, intense heat, great thirst, red eyes, a burning hot face, and a rapid strong pulse; corresponding with a similar strong rapid action of the heart, confront the observer, he cannot hesitate, unless he be an ass, or a reckless hunter after notoriety in an extraordinary way, to banish all thoughts of stimuli, and save life by a proper antiphlogistic treatment. The treatment should not irritate, for medicinal irritation added to the inflammation which constitutes fever would aggravate the fever, and transfer it to the brain. Typhus fever invades individuals and localities from two chief sources. It is the sequel or attendant of continued fever which is essentially inflammatory and anti-putrid, or it arises from marsh miasm or human effluvium. It has its own generic cause and source: therefore it becomes self-creating and self-acting, putrid in its essence, rapid and prostrating in its course. When typhus, or rather the typhoid character, appears towards the end of continued fever, it is simply the result of the strong febrile excitement that characterises continued fever. Typhus therefore, as a sequel of continued fever (which is the matrix, or type of all other fevers), is more inflammatory, less prostrating, and not so rapidly putrid and fatal, as typhus produced by *marsh miasm*, or human *effluvium*. In the former, typhus is more or less inflammatory, like its parent, *continued fever*, but in the latter case, that is to say, typhus from contagion is congestive, not inflammatory, prostrates at once all the vital powers, and buries in Lethe the sensorial or nervous energy, upon which all the other vital functions depend. In the *delirium* of continued fevers, even when typhoid symptoms first appear, there is power, energy, delirium ferox, the delirium of strength, of an inflamed brain, of an inflamed accelerated circulation. In fact, continued fever is as essentially inflammatory, as inflammation *per se*. This inflammatory character, whose manifestation is high-fever, continues to the end; unless the working energy which is plus, be reduced by skilful treatment to equilibrium. The great danger in both fevers is this, that the equilibrium is destroyed, and the inflammation of continued fever, or the congestion of typhus, attacks the vital organs *eccentrically*, *irregularly*, one after *another*, one more than another, and if not prevented by treatment, the disease attacks finally, and fatally all together. Such is the nature of inflammatory fever, and such is the action of typhus—of *real* typhus—the product of marsh miasm or human effluvium. A putrid prostrating typhus, with low muttering delirium, great debility, a sinking of the patient in the bed, are sure signs of death. Now in the case of the Prince, the fever, according to the bulletins, continued uncontrolled for nearly a month, and his strength remained unimpaired. If the case was typhus from the beginning, high fever and corporeal strength could not coexist with such a knock-down and prostrating visitor as typhus. But, as pyrexia (high fever, inflammation and strength), are the positive symptoms, the general and diagnostic signs of continued fever, the Prince must have had inflammatory fever; that is to say, continued fever in the beginning, and towards the end typhoid symptoms, the invariable attendants of inflammatory fever; whenever the primary excitement, which I have described, is not arrested or moderated by an unirritating, skilful treatment. I must not let this great subject carry me too far, and I conclude with the hope that the case of the Prince, may be published as due to the Profession and the public good. The science of medicine, rightly understood, is the science of life. It supplies abundantly sure principles of theory and saving methods of practice, and any valuable contribution to a cause so noble, and so glorious, would be a work of beneficence indeed.

Hospital Reports.

ST. GEORGE'S HOSPITAL.

Paracentesis Thoracis.

MUCH has been written recently on the question of tapping in cases of pleurisy. The tendency now is, says Dr. H. Fuller, to operate prematurely, before the improbability of obtaining absorption of the effused fluid has been made out. The dread as to the admission of air into the pleural cavity he considers *fallacious*, and often leads to the failure of the operation. The chest is tapped under water, and various ingenious instruments made use of. He objects to all such both theoretically and practically. They complicate a very harmless operation, and the admission of air causes no injury to the patient. Such contrivances cause pain when suction is used, and it is quite impossible to *empty* the chest by means of suction, which ought to be aimed at. Air must enter to accomplish this, unless the chest wall were to sink in, or the viscera be displaced, except in the very early stages of pleurisy. In many cases occurring in practice, the lung has become compressed, being carnified and incapable of speedy expansion, or bound down by adhesions, so that expansion can only be effected by natural methods. In such cases it is often impossible to draw off more than a small quantity of the fluid. The walls of the chest being rigid, its contents will only run out if air be admitted, as is the case in a cask. The chest walls will fall in, the diaphragm will rise, the mediastinum will encroach on the affected side; and up to the point to which they are capable of yielding there is no necessity for the admission of air, inasmuch as by their displacement the space previously occupied by the fluid which is drawn off is at once filled up. But, provided the lung is permanently or even temporarily incapable of expanding, it is physically certain that without the admission of air the fluid contents of the pleural cavity can only be drawn off to the extent to which the walls of the cavity are capable of falling in to supply the place of the fluid withdrawn. If, in contravention of this physical law, an attempt is made by forcible suction-syringes to draw off still more of the fluid, injury to the patient must ensue; for there must be a forcible dragging and stretching of the walls of the chest. Within six months four cases were tapped at St. George's, and air was not excluded, and they all did well. Dr. Fuller advises us to tap when dyspnœa is urgent, and it becomes evident that remedies fail to get rid of the effusion, as low down as possible, with a free opening, so as to let the chest empty itself freely. If the fluid is serous, close the opening with carbolic plaster as soon as the operation is finished and the fluid evacuated; if purulent, the wound is to be kept from closing, and drainage employed if necessary, whilst the patient is fed generously.

ST. MARK'S HOSPITAL.

MONDAY, MARCH 11TH.

Two operations for lumbar colotomy were performed—the first a girl about 14 years of age, of a syphilitic cachexia and extensive ulceration of the rectum; the second, a man aged about 30, suffering from malignant disease of the rectum. Mr. Allingham performed two operations for fistula in ano, in which he laid the collateral sinuses freely open from end to end, after his usual method.

GUY'S HOSPITAL.

TUESDAY, MARCH 12TH.

AN interesting operation for the removal of a polypus from pharynx was performed. A free incision was made, commencing just above the right ala nasi, and continued downwards through the lip. An incisor tooth was extracted, and a large triangular piece of the superior maxilla was removed in order to reach the tumour, which was attached to the base of the skull. The portion of bone was replaced, and held in its place by sutures; the wound was neatly closed, and scarcely any disfigurement of the face perceptible.

An amputation at the knee-joint for gangrene of the foot and limb supervening upon a fracture of the pelvis was next in order. The operator did the long anterior and short posterior flap operation with removal of the patella.

The next case was an amputation of the thigh at the lower third for chronic disease of the joint. Flaps of periosteum to cover the ends of the bone were made by the operator in this case.

The next and last case was the division of a cicatrix on the anterior surface of the neck, resulting from an extensive burn. Subject, a small boy.

RICHMOND SURGICAL HOSPITAL.

(Cases under the care of Mr. William Stokes.)

(From Notes taken by Mr. A. Jolly.)

Wound of the Radial Artery.—Deligation.—Recovery.

William Kane, æt. 35, by occupation a carman, was admitted into the Richmond Hospital under Mr. Stokes's care on Saturday night, the 20th of January, 1872, suffering from a wound on the front of the lower third of the left forearm, which he had received about half-an-hour previously to his arrival at the hospital. The wound was the result of a blow of a broken plate inflicted by his wife, he being at that time in an inebriated condition. Immediately after the wound was inflicted smart bleeding was observed coming from it; attempts were then made to stop it by the application of cold compresses, but this failed to arrest the hæmorrhage. The patient then attempted to walk to the hospital, but while on his way he became weak, and fainted in the street. Some passers-by, seeing him in this condition, brought him, on his partly recovering, to the hospital. On examination, he was found to be very weak and inclined to faint. He was incapable of giving a clear description as to how the wound was inflicted. It was about an inch in length, situated over the left radial artery in its lower third. The hæmorrhage having then ceased, the edges of the wound were brought together by adhesive plaster and a compress and bandage were firmly applied. The patient was then urged strongly to remain in hospital in consequence of the great probabilities of a recurrence of the hæmorrhage, but he refused positively, and returned home.

On January 24th, at four o'clock a.m., the hæmorrhage came on. He was again brought to the hospital. The hæmorrhage was on this occasion effectually arrested by acupressure applied by Mr. Vesey.

January 26th.—Hæmorrhage again returned, and deligation of the artery at both proximal and distal ends of the wounded vessel was determined on by Mr. Stokes. The operation was accordingly performed, and as is nearly always the case under such circumstances, considerable difficulty was experienced in securing the distal end, owing doubtless to retraction, hæmorrhagic infiltration, suppuration, and sloughing of the wound.

January 28th.—No return of bleeding since the operation was performed; cold water dressings applied.

February 2nd. Both ligatures came away; wound has a more healthy appearance; dressings applied daily same as before. Patient complains of some pain in left axilla.

February 4th. — Free suppuration from the wound. There is evidence of a fresh abscess formation in the upper part of the forearm. This subsequently communicated with the wound.

February 13th.—Wound healing slowly.

February 26th. Another abscess formed in middle finger, which was opened by Mr. Stokes.

On March 2nd the patient was found to be suffering from erysipelas of the hand, forearm, and arm, accompanied by great pain and constitutional disturbance.

March 6th.—The erysipelas has subsided.

March 9th.—All unfavourable symptoms have subsided, and the patient is now convalescent.

Transactions of Societies.

MEDICAL SOCIETY OF LONDON.

March 11th, 1872.

THE NEW PRESIDENT.

On taking the chair, Mr. **Thomas Bryant**, F.R.C.S., delivered a short address. He acknowledged the honour conferred upon him, and felt it more on looking at the list of great men who had preceded him, and recollecting that his revered father had been twice president of the same society. This society, now a century old, had been both father and mother of newer societies, whose success no one regretted. The society was comprehensive in its objects, and embraced all branches of the Profession. The evils of specialism were dwelt upon, although it was admitted at the same time that practised by men of culture in a broad and scientific spirit, specialism was productive of good. The importance of the study of pathology was then demonstrated by reference to enlargement of bone and to aneurism. The clinical value of pathological knowledge was illustrated by reference to struma and scrofula so-called. In conclusion the President dwelt upon the friendliness and charity which had always characterised the society.

Mr. J. F. **Clarke** asked, as the oldest Fellow present, to be allowed to remark upon the unprecedented occurrence of father and son having occupied the presidential chair. He almost thought he heard "more than echoes run along the wall." Mr. Bryant, sen., was a good and worthy example, which he felt confident his son would endeavour to follow.

Mr. **Maunder** exhibited a portion of the temple bone, taken from a child nine years of age, who had had measles some time ago, and otorrhœa ever since. Attacks of pain, giddiness, and vomiting occurred from time to time, but at last to these symptoms was added coma, and the child died. At the *post-mortem* an abscess in the cerebellum was found. Mr. Maunder inquired whether any Fellow could suggest treatment in such cases, and especially whether the incision of the tympanum was admissible.

Dr. **Sansom** mentioned a corresponding case, which appeared to have followed a blow. The eyeballs were protruded. Dr. Sansom thought at first it was cerebritis with abscess. At the autopsy the brain was found entirely free from disease, but there was pus along the orbital nerve and in orbit. There was also pus between the periosteum and the body sphenoid, there was no disease in the temporal bone.

Mr. **Weeden Cooke** remarked on the frequency with which otorrhœa followed measles, scrofula, &c., and referred to Mr. Gay's proposition to trephine the mastoid cells in cases of abscess of the brain.

Mr. **Gay**, dwelling on the fatality of cases of the kind, insisted on the propriety of trephining the mastoid cells when symptoms of cerebral abscess arise. He related an illustrative case, and pointed out that in one part of the meatus the lamina is very thin, and may readily be punctured to give vent to pus.

Mr. **Hinton** thought Mr. Gay's proposition one requiring serious consideration, especially seeing that the primary seat of lesion giving rise to cerebral abscess was in the ear according to prevalent views. The invidiousness of such cases, as shown by long standing discharge of ear, was remarked upon. Early treatment directed to ear was often successful. The membrana tympani seemed to be more tolerant of mischief in early than in subsequent life, and incision might often be found valuable. Mr. Hinton would incise the tympanum in cases of scarlet fever, when there were indications of serious distension.

Mr. **Gay** explained that his remarks had reference to primary abscess of cerebellum, in which otorrhœa subsequently came on.

The **President** then opened a discussion on the treatment of aneurism, and showed a laminated clot which had been figured for many years for the case of Mr. Keys, and some other specimens and drawings. He mentioned a case of aneurism of cœliac axis, which was treated by compression of efferent vessel, viz., aorta, just above bifurcation, in which a good result as regards lamination was obtained, but the patient died from peritonitis caused by pressure. The question of temporary pressure of efferent artery was introduced, and he thought it might be valuable. Forced flexion was sometimes objectionable, on account of the great pain which it caused. Mons. Liegor's statistics of popliteal aneurism by flexion were given. A cure by flexion was obtainable only in one-fourth of these cases. In some cases treatment by flexion was unsuccessful. What were these cases? We must seek this knowledge through pathological investigation. The President thought such cases were probably of traumatic origin, either discoverable or not, or of rapidly forming aneurism. The success of practice in Guy's was in ligature 1 death in 24 cases; in pressure 17 cases, 11 successful, 6 failed, and were treated by ligature. Perforation of mastoid cells was often decidedly called for, and ought to be resorted to, as it was, as a rule, a very successful operation. He then gave the following

PROPOSITIONS ON ANEURISM.

1.—From the pathological evidence we possess it appears that for the cure of a sacculated aneurism its mechanical closure by a clot is all that is required. The typical laminated clot only takes place when the cure is chronic, it is in no way to be considered as an essential part of the cure, although to a degree most clots are laminated.

2.—From pathological evidence before us it likewise seems probable that the coagulation of the blood in an aneurismal sac may be obtained by obstruction either to the afferent or efferent vessel; that distal as well as proximal pressure are both capable of producing the same result.

3.—Accepting the facts as proved, that obstruction to the afferent vessel may be secured by forced flexion of an extremity as well as by digital or instrumental pressure, clinical evidence is wanting to determine the conditions under which these forms of practice may be expected to succeed separately or combined.

4.—Accepting the fact likewise that all aneurisms of the extremities cannot be successfully treated by forced flexion and compression of the afferent artery, it is desirable to know under what circumstances such a plan of treatment is inapplicable.

5.—Acknowledging also the great principle of practice which most surgeons now accept, that no large vessel should be ligatured for aneurism unless the treatment by compression in one of its forms has failed or is inapplicable, it is desirable to know under what circumstances the treatment by ligature should be primarily applied.

6.—Complete obstruction to the afferent vessel appears to be the more rapid mode of cure than the incomplete.

7.—Digital pressure to cover the artery and mechanical pressure by a weight to save muscular force seems to be the best mode of applying pressure when it can be carried out.

8.—Mechanical pressure should only be had recourse to when digital cannot be employed, the elastic pressure being probably its best form.

9.—When the afferent vessel cannot be occluded by surgical means, there is reason to believe that the same coagulation in an aneurism may be secured by the occlusion of the efferent, either by pressure, ligature, or other means.

10.—The tubular or fusiform aneurisms are probably cured only by some inflammatory action in the walls of the dilated vessel, the fibrinous secretion being probably of the plastic kind, bearing a certain analogy to the adhesive process in other parts, as pointed out by Luke (*Med. Times and Gaz.*, 1845). But this subject is not one upon which I propose to raise a discussion.

Dr. **Peter Allen** enquired of Mr. Maunder whether pus escaped externally or was retained, as this made a material difference as regards treatment. He remarked upon the absence of facial paralysis, and thought Mr. Maunder's case an example of catarrhal inflammation. Dr. Allen dissented from Mr. Gay's views that abscess of cerebellum was common in disease of petrous portion of the temporal bone, and thought that in three cases out of four it was in the middle lobe; he agreed that perforation of the tympanum should be resorted to when there was evidence of pus in the cavity of the tympanum.

Mr. W. B. **Dalby** remarked upon the pathology, and said according to Toynbée and other writers the cell of the drum was the seat of disease, and that abscess of the cerebellum was the result, in which view he agreed. He related a case of cerebellar abscess, in which there was no caries of bone, but some discolouration. He thought the pathology of these cases was by no means clear, the formation of abscesses a little remote from the diseased bone might be due to thrombosis.

Mr. **Pennefather** thought that in long standing otorrhœa very little membrana tympani was left to perforate, the trephining of mastoid cells for abscess was rendered difficult on account of doubts surrounding diagnosis. The mode of treatment, he thought, was to aim at getting a clot, not necessarily a laminated clot, but a clot, and therefore the interruption of the current must be complete. Digital pressure was undoubtedly the best, though difficult to obtain. Failing that, elastic mechanical pressure was to be resorted to.

Mr. **Henry Smith** remembered the introduction of the treatment of aneurism by pressure, but thought the conclusion now arrived at was that although treatment by pressure on efferent side of vessel was successful, the plan of ligating was more freely resorted to, and more generally fortunate, as regards pressure on efferent side of vessel. Mr. Smith differed from the conclusions arrived at by the President. He commended the plan of digital pressure as valuable where it can be obtained.

Mr. **Gay** thought that on the whole few plans of treatment excelled the old-fashioned one of treatment by ligature. The seat of the aneurism was an important one in choice of treatment, in some cases ligature not being applicable, in others pressure. With reference to pressure on efferent vessel Mr. Gay thought it often equally efficacious with pressure on afferent; pressure on efferent side of large vessel was most likely to succeed.

Mr. **de Meric** thought that milder means should always be resorted to at first. He agreed with the plan of intermittent but complete pressure advocated by the President. He expected to have heard something about the treatment of aneurism by electricity, He wished also to know the President's opinion as to the treatment of aneurism by emptying the sac and tying both ends of the vessels.

Mr. **Maunder** mentioned a case in which he successfully employed digital pressure for popliteal aneurism, by pressing both thumbs over the head of the femur.

At this point the discussion was adjourned until Monday, the 18th inst.

The ninety-ninth anniversary was celebrated at Willis's Rooms on March 8th, when sixty-four fellows and visitors sat down to dinner; the chair being filled by the President, Dr. Andrew Clark, who was supported by the Presidents of the College of Surgeons, the Medico-Chirurgical, Obstetrical, and Pharmaceutical Societies.

The usual loyal and patriotic toasts having been drunk with all enthusiasm, the President gave the toast of the evening, "The Medical Society of London," coupling with it the name of the President elect, Mr. Thomas Bryant. Dr. Clark showed that financially the Society was never more prosperous than at present, and urged the desirability of a close adhesion to clinical and therapeutic work. He reminded the Society of its approaching centenary, when it will become necessary to provide new and ample accommodation for the increasing growth of the Society, and expressed a hope that the Fellows would make an effort to build a house for themselves.

The toast was cordially received and responded to, as were the other toasts of the evening. We have already given notes on the subjects alluded to.

◆

CLINICAL SOCIETY OF LONDON.

Friday, Feb. 23rd, 1872.

Mr. **Thomas Bryant** read a paper on

TWO CASES OF RECTO-VESICAL FISTULA SUCCESSFULLY TREATED BY COLOTOMY.

The first was that of a gentleman, æt. 64, who had had diarrhœa, tenesmus, and the passage of blood and mucus three months before he had begun to pass fæces in his urine. Colotomy was performed on August 16th, 1869, with complete relief. The patient was up and out of the house in a month. At the present time he passes his urine naturally, and the motions through the loin, some little urine at times finding its way into the rectum and upwards through the loin. The ulcer in the bowel has long healed, the fistula alone remaining. The second case was that of a gentleman, æt. 49, who for three years had been passing urine and fæces by the urethra. He was much reduced in health, and most miserable from the local pain and irritation caused by his disease. On the 5th of July, 1870, colotomy was performed, complete relief resulting almost immediately. In three weeks he was up, and in another week out. Six months later he reported that he was getting quite fat, that he was free from all pain, and that his only trouble was the passage of water at times up the bowel through the artificial anus. At the present time, a year and a half after the operation, he remains well. In both these cases Mr. Bryant remarked that there was good reason to believe that the ulcerative action that had caused the fistula was of a simple nature, and had commenced in the rectum; that after the operation the ulcers soon healed, although the fistulous opening remained. He stated that the two cases in every way supported the remarks appended to a similar case which he had read at a sister society, and which were published in the *British and Foreign Quarterly Journal*, 1869, and still more prove the truth of Mr. Holmes's remarks on the same subject recorded in the Med.-Chir. Transactions, 1869-70. Mr. Bryant added that these cases, and all others he has had since 1868, have made him think more highly of the oblique incision in the operation than the transverse.

A very interesting discussion took place, in which Mr. Heath, Dr. Habershon, Mr. Hulke, Mr. Carter, Mr. Maunder, Mr. Barwell, and Mr. Thomas Smith took part, and Mr. Bryant replied.

EPIDEMIOLOGICAL SOCIETY.

FEBRUARY 14TH, 1872.

DR. SEATON in the Chair.

ADDITIONAL NOTES ON THE CHOLERA EPIDEMICS ON THE EAST COAST OF AFRICA.

By JAMES CHRISTIE, M.A., M.D.

IN a previous paper read before the Society during session 1870-71, Dr. Christie had given an elaborate account of the prevalence of epidemic cholera on the East coast of Africa. The present paper had for object to correct certain dates in that paper and convey additional information of the movements of the disease. The dates of the different recorded epidemics on the east coast are as follows: 1st epidemic, Dec. 1836, Jan. 1837; 2nd epidemic, 1859-60; 3rd epidemic, 1865; 4th epidemic, 1869-70. The chief interest of the present paper rested in the additional light cast upon the beginnings of the third and fourth epidemics. By carefully prosecuted inquiries among native traders on the mainland it would appear that the epidemic of 1865 probably reached the east coast from Asebera, on the south coast of the Gulf of Aden. The disease, it is believed, was introduced into Asebera about the same time that it was introduced into Makalla, on the south coast of Arabia. Makalla, it will be remembered, was the first definitely ascertained starting point of the north westward extension of the epidemic of 1865. At the break up of the Asebera fair, doubtless the malady followed the tract of the great southern caravan route across the Somali country to Gananah and Aarderah on the river Jub. From Aarderah, still following the trade route, cholera extended to Arava on the east coast, and thence it spread northwards to Merka and Makdesha, and southwards as far as Mombassa. The fourth epidemic (1869-70) reached the coast from the interior of Africa. A large caravan which left Sangani for the Masai country in November, 1868, reached its destination on the forty-ninth day of journeying, and then heard of a virulent disease, which proved to be cholera, in the Somali country to the north. The Masai had made a raid on the Somali, and the expeditionary party contracted the disease and brought it back with them into their own country. Subsequently, the malady spread into the district intervening between the Masai and the east coast, and appeared at Tanga and Pangani, and from these coast towns began that wide diffusion along the coast which Dr. Christie described in his first paper.

In the discussion which followed the first paper, Mr. Netton Radcliffe suggested that the cholera prevalent in the Masai country at the close of 1868 and beginning of 1869, was the continuation of the epidemic of 1865-68 in Abyssinia, and which in 1868 was known to have spread into the Galla country, in the direction of Aarea, the great centre of commerce for this part of Africa and for the east coast north of Zanzibar, and the further details given by Dr. Christie tend to confirm this suggestion.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, MARCH 20, 1872.

INFANT LIFE PROTECTION BILL.

"BLOW the trumpets, beat the drums!" At length the Government has yielded to the passionate solicitude of legislators and constituencies, and consented to postpone sensational legislation to the more useful requirements of social reform. A Bill for the Better Protection of Infant Life stood first on the paper for Wednesday morning's sitting. The House was to meet at 12 o'clock. On the occasion of the Ewelme appointment, which was of not much matter to the country, the House was well filled; on the Collier debate, thronged. What will it be, then, on a really important subject for legislation—a subject affecting the primal duty of all government, the protection of the "rights of person" in the feeblest and most dependent portion of the community—the human infant? Have not dark hints been whispered abroad for years of foul deeds done to the helpless progeny that first see life in some *bizarre*, out-of-sight lying-in establishment? Have not nurseries of women, to whom these self-constituted midwives farm these wretched babes, sent out strange sounds of infant wailing during the midnight hours; and have not scared servant girls every now and then fled in terror from these scenes, and told horrible tales of starved and drugged, or tortured and mis-shapen babes slowly being done to death? Have not the statistics of babes dropped down areas, and laid in the dead of night in dust-bins, or waste lands, amounting in one year in the metropolis alone to 270, added to the apprehension that even yet in 1872 there is more than a waste of human life—there is a system of evil doings to helpless infancy in this great centre of civilisation enough to make the most heedless fop look grave, and the boldest man feel doubtful? Ah, thought we, there'll be a full House this noon, at any rate. So, early as we can gain admittance to the lobby, we present ourselves at the accustomed door. The officer puts out his hand. We thought so—the House full to overflowing! "Haven't you a corner seat?" said we anxiously. "House can't be made," was the cool reply; "only 29 with the Speaker." At that moment Mr. Kinnaird, M.P. for Perth, enters, and we peep in. "What a beggarly account of empty benches!" we exclaimed. Out comes the "Mace," looking round, and, seeing a man at the door, asks if any member is in the lobby or about. A couple of members and an Under Secretary are hurried in. Another quarter of an hour, and again Mr. Speaker counts aloud 36. Half an hour is lost, and in walks one, and, following at a lapse of five minutes, two more drop in, and Mr. Speaker takes the chair to the tune of a feeble and somewhat ironical cheer. Oh, morning newspapers! How can you tell such fibs about the interest taken in questions of social and sanitary reform? Did you ever go into the Rotunda of the Bank three days before dividends are paid, or into the pit of a theatre on a wet morning, during a dull rehearsal at the fag end of the Christmas pantomime season? Very well, that was the sense of enthusiasm pervading the House on this famous Wednesday morning debate. With heavy heart we moved up-stairs to our nook, and Mr. Charley had already begun, and was saying that "a Select Committee had already sat for thirteen days, and examined twenty witnesses, who had practical knowledge of the system of putting out children to nurse for hire. His honourable friend, the member for Edinburgh, had last season attempted to enforce a compulsory registration of births and deaths, and he only withdrew his Bill on the understanding that the Government would introduce a Bill on the subject. The Committee had recommended inspection of lying-in establishments, but felt it advisable to leave this to the Health Department of Government. The Bill provided that persons who for money placed themselves in '*loco parentis*' towards two or more children for above a day should obtain certificates of ability to take such charge, the licence to be annually renewed. A register book of such infants was to be produced on the order of a justice of the peace. A coroner's inquest to be held on every infant dying in the nurse's charge, unless a registered Medical man certified the death as one arising from natural causes. Relatives and guardians of children whose parents were abroad, and infant homes and foundling hospitals, to be exempted from the operation of the statute. The Bill asked for no public money, unlike the Bill of the preceding year. The public were familiar with the Bristol baby farmer, Margaret Waters, and the hon. gentleman anticipated (vainly, we fear) that the apathy shown by the House towards mere party or political questions would yield to earnestness and interest when such a question as that—social reform—was brought distinctly before it. He moved the second reading."

The hon. member for Horsham (Mr. Hurst) followed, complaining that the action of the Bill did not extend to those who entrusted their babes to baby-farmers, as well as to the latter. He wished the Bill to contain a clause placing lying-in houses under the licensing restriction. The Bill (he contended) made no rovision to secure the fitness of the house of the nurse, who might live in a cellar. He wished responsibility to be thrown on the coroner, and not transferred to the Medical practitioner; but all these defects he hoped to amend in committee.—

Mr. Dalrymple (member for Bath) observed in early life, in a large union in the metropolis, a wholesale massacre of infant life, and had witnessed in infant hospitals painful results of cupidity and mismanagement. He thought the payment of a lump sum should be made illegal, for this almost certainly implied the death of the child. It was necessary to take notice of the establishments where the fruits of vice and crime were concealed and rarely came out alive. There was another species of infanticide—not indigenous, he trusted, but from across the Atlantic or the Channel—where the infant was never born alive; and he would urge the Government to take steps to bring these offenders to condign punishment. He thought the provision for inquests required strengthening. He alluded to improper food and narcotic drugs as the two fruitful sources of infant mortality, and hoped that the verdict of the inquest would throw light on this phasis of the question also. He accepted the Bill as an instalment.

Dr. Brewer (member for Colchester) would remind the hon. member for Horsham that to proceed against a parent for putting out her child to nurse would in many, he hoped in the majority of cases, be unjust and unwarrantable. A number of innocent persons were, from their poverty and from their being compelled to go out to service, forced to entrust their children to others to nurse. It had come out in evidence at the Committee, that many to whom these poor women had given their children up to be nursed treated such little charges with tenderness and truly maternal affection—more still, with a fair amount of motherly supervision. It was a mistake, he thought, to conclude that the majority did not live above the law, and those for whom the restraints of the Act were provided, it must be admitted, were persons whose dealing with one child committed to their charge would be fraught with well-nigh as much danger as if charged with two or several infants, for evidence was not wanting of the ominous facility with which they rid themselves of their nurse-babes one after another without exciting the suspicion this mortality ought to have challenged. There had been evinced a strong feeling, which continued to be entertained by a number of associated benevolent ladies, not to interfere with the humbler classes in their dealing with their children; and those who had the charge of the Bill felt it would be impossible for them to carry a Bill that would satisfy all the demands of those who had carefully studied the subject. Periodical inspection had been admitted by the promoters of the Bill as of no secondary importance. Again, the ladies pleaded that the dread of exposure, which was the keenest prompter to the mother to send out her child to be nursed, would increase the danger of infanticide at the hand of the mother herself. He was not prepared to endorse this view of their duty or of the operation of such a provision. The member for Horsham had complained that no care had been taken to secure that the lodging of the baby-farmer should be suitable, but if he read the schedule he would find that her ability, which had to be certified, extended to lodging as well as food. His friend, the member for Bath, had desired that the payment of a lump sum should be prohibited by statute, but this would not accomplish what his hon. friend had desiderated. It was a fearful temptation to receive a lump sum in payment of all demand, but it was the only course practicable where the parent had to go abroad for an uncertain period, and it had been found that the risk of the child being left in the hand of the nurse without any remuneration, was at least as great a danger and a greater injustice. It had been admitted the practice of giving a lump sum ought to be discouraged, but he could not see his way to a statutory prohibition. It was evident that the reception of an insufficient sum evinced a criminal intention, but the Bill would really attack the evil by the operation of the clause, which required an inquest to be held on the death of the nurse-child. The compulsory registration of all births and deaths was determined upon, and he had hopes the licensing of lying-in houses would be undertaken by the Government. In the mean time this Act called for by the evidence which existed of criminal neglect of infant life, of criminal intention proved before the courts of the country, proved by the clergy, by the police, by Medical men, amply justified the legislation they had proposed. It was not necessary to stigmatise with criminal motives, those to whom the care of infants was committed, it was sufficient to show that the fear of ill-treatment was a reasonable one, and if so, considering the human infant as the most helpless and defenceless of the community, it was eminently fitting the legislature should step in and yield the protection required. The step was a tentative one, and they did not want to go beyond the proved necessities of the case, but to stop short of this was to stop short of an obvious duty.

Mr. Walpole, who had been the chairman of the Select Committee, said that a full knowledge of the children put out to nurse was essential, and also of the places to which they were sent, for whilst infant mortality under twelve months was, under the most favourable circumstances, only 16 per cent., it was under baby-farming as high as from eighty to ninety in the worst cases.

The evil must be met by registration, and dealing with all the circumstances attendant on the clandestine delivery and transmission of the children to nursing houses; the tracing of the movements of the baby-farmers, and dealing with children left in the streets, and buried and got rid of without notice was the only method of reaching the root of the evil.

Mr. Bruce expressed that the suggestions made should, on the next stage of the Bill, receive the consideration of Government.

Mr. Henley feared that the increased burden this Bill would throw on the poor women would offer a premium to do things which ought not to be done, and which they all deplored.

Dr. Playfair said that, without altering the laws relating to bastardy, seduction, registration of birth, and verification of deaths, the root of the evil would not be got at. He had made a report twenty-seven years ago showing that of 50,000 illegitimate children, 30,000 died in the first twelvemonths. Criminal negligence and ignorance were the cause of that. The natural food of infants was milk; to give a babe oatmeal gruel, or food it could not assimilate, was to starve the child, yet the coroner was unwilling to bring in such a verdict. The Bill would encourage respectable people to take up the trade of nursing which the scandals at present connected with it hindered. If £5 or £10 were offered for bringing up a child 300 answers would be received in reply. The motive was gain, not benevolence; what must ensue? 276 children were found annually forsaken and left in the streets of London. The coroner's inquests would prove against a nurse ignorance, if ignorance were there, and this would put a stop to her trade. The Bill did not go as far as the promoters desired, but if it were found not to go far enough, it might and would be strengthened.

Mr. Winterbotham felt strongly that Mr. Henley's remarks were just, that an effort to remove the present evils might produce greater evils; the Bill would drive the criminal class of nurses to greater secrecy and perhaps give them stronger motives for crime. He feared that poverty was one of the great causes of the non-criminal neglect of children; however, that and the penalties for infringing the measure would be matters for the consideration of honourable gentlemen in committee.

Thus the debate closed, and the Bill was read a second time. We don't say the House was lively, but by the time the member for Horsham had spoken it filled moderately.

It is a mere delusion to be impressed with the notion that the House is in earnest in social or sanitary reforms, it is a fiction and not a pleasant one either. A mere buffoon gesticulating like an old-fashioned telegraph and uttering "Joe Millers," twenty times reiterated, will keep the benches full and wide-awake. A party quarrel of the thinnest substance will cram the House to suffocation,—a personal retort will move the honourable members to ecstacy, from the measured Polyphemus to the weakest Sybarite; but a Bill for social advancement, or the regulation of social disorders has much the same effect as drilling holes in a tun of sour wine, it leaves its cask by every pore. Those who are weaving golden nets to catch a profitable haul of social or sanitary measures had better think twice about the where, when, and the wherewithal they may carry them into harbour safely. The flesh of the House is very weak, and what is worse, the spirit is anything but willing.

◆

THE SURGICAL BARONETCY FOR IRELAND.

The Profession in Ireland is apparently of one mind as to the force of its claims to a royal distinction, now that the services of the Profession to the Crown are being recognised elsewhere by the ennobling of Sir William Gull, and the decoration of Sir William Jenner. It is not for us to analyse the motives of diplomatists, or their reasons for restricting all the Medical honours to one side of the Irish Channel, but any one who holds intimate intercourse with the Profession in Ireland cannot fail to be aware that it is fully expected that that restriction will be broken through, and that the granting of a surgical baronetcy in Ireland is a foregone conclusion.

Already, indeed, nothing is canvassed but the question who shall be the recipient of the coming honour; and Irish Medical men seem to live in daily expectation of reading in the *Gazette*, the name of one or other of those whose claims are now under debate.

It seems to us that that list of eligible claimants is an extremely narrow one, and that the letter-writers in the daily papers, who either exercise their ingenuity in inventing new candidates, or their flunkeyism in beslavering their pet surgeons, do so without knowing or considering the circumstances. In the first place it is to be presumed that no physician will seek or expect to receive the anticipated distinction. The Profession of Medicine has had at all times the lion's share of such distinctions in Ireland, and at the present moment the only baronet in the Irish Profession is a pure physician, while the only surgical baronetcy which Irishmen have ever held has remained many years in abeyance, awaiting for its resuscitation an occasion like the present, and men as worthy as those who might now be selected.

If it be assumed that the expected honour will be given to a Surgeon, the choice is narrowed, not by any want of scientific or skilful practitioners, but by requirements which it is understood are always imposed as necessary qualifications.

If we were at liberty to seek amongst the leading surgeons in Ireland we should find the selection a difficulty, and in the foremost rank of worthy men would be found, if the competition were an open one, the Professor of Surgery in Trinity College, and the President of the Royal College of Surgeons, Mr. Colles, and Dr. Robert McDowell.

It is, however, a current idea, and one which is justified by the experience of honours already granted, that the Crown requires from those whom it ennobles very substantial monetary guarantees for the maintenance of the title after the death of its first holder. We have no evidence whereby to assess the amount of this guarantee, but it is commonly understood that any person on whom it is proposed to confer a baronetcy must be in a position to alienate from his own control an income of several hundreds a year for the endowment of his successor in the title, and to adduce proof that he possesses a handsome personal income. If this impression be correct, it is obvious that few working surgeons, however deserving they may be in every other respect, will be ready to do injustice to other members of their families, and to incur the increased expenditure incident to a title, for the sake of a transient honour to themselves, and the transmission of an expensive heir-loom to their successor.

Assuming then that a surgical baronetcy is closed to the hopes of men with large families, or moderate incomes, we have made our selection from the very few men who are believed to be in a position to conform to the financial requirements of the occasion, and who in addition are the possessors of so high a surgical character as may do honour to their ennoblement. In making such a choice we don't hazard any guess at the financial position of practising surgeons, and we may possibly be doing an injustice to some of our brethren who may be able to enter into the competition,—financial and scientific.

Mr. Adams, as we have said, is a man who needs no other recommendation than his name and scientific rank, and there is no surgeon in Ireland who would not stand aside from any race in which he was a competitor. Should he not ask or accept the honour, we adhere to the opinion that Mr. Porter occupies the next position behind him. As the Queen's surgeon, he could hardly be passed over; as the senior surgeon of almost the premier surgical hospital in Ireland, his professional office places him in the highest surgical rank; as a successful practitioner, his position is beyond cavil; as the possessor of independent means rumour gives him credit for all that may be necessary to sustain a title; lastly, as a man of honour and untainted personal reputation it is sufficient to say that no adverse whisper has in the contest of opinions yet been heard. Many other men may and do possess claims as well-founded on one or more of these grounds, we know of no other who combines the whole.

◆

SWISS PROFESSORS AND STUDENTS.

THERE is about Switzerland a charm that those who know can alone appreciate, and with all our alleged insular prejudices the British people have never altogether steeled themselves against the delights of foreign society. A scene known pretty well to travelled men is reported with great effect by the *Standard's* correspondent at Berne, and as Medical professors and students are this time the actors, we may be excused for availing ourselves of the opportunity of laying before our readers a striking feature of continental academical life. Two professors of Berne have accepted appointments at the University of Strasbourg, and so the excellent school of which they are ornaments, of course loses them, though even then Berne will have several well known teachers. Professors Lücke and Klebs being on the eve of leaving, the Medical students decided to give a "Fackelzug" in their honour. This Fackelzug is the highest compliment which students can pay to their professors, and is only very rarely given. In ordinary cases the students content themselves by choosing a dozen of their number to give a serenade; but a Fackelzug is a matter not lightly to be attempted, as it requires much preparation and numerous preliminary meetings. It is thus described by the correspondent:—

> In Berne the students are divided into different societies, or clubs, the members of which are distinguished by their different-coloured caps and ribbons. Each of these clubs has its captains and sub-officers, who wear swords and broad sashes of glowing colours, and require strict obedience from their comrades. There are also flags and banners in profusion, borne by other proud members, many of whom look as though their burden was by no means a light one, or that the beer had got into their legs, for they stagger rather ominously, while at the head of the procession comes the band, which is made up of members also, and generally plays excellently. Often behind the band comes a student bearing an immense pipe, which is filled with tobacco, and which he slowly smokes as he marches along. Behind him come two others, bearing cornucopias, some 3ft. high, which are filled with flowers. Nothing can be more picturesque than to see one of these clubs marching up the Kramgasse on a summer evening on their way to the Enge, or some other of the numerous pleasure resorts round the town, headed by their band. When the music stops, some one with a good voice starts a "lied," in which the rest join as they hurry along.
>
> Last night, the clubs who took part in the demonstration, were the "White Caps," and the "Orange Caps," which are mainly composed of medical students, and number about 250. The two professors live in the Christoffelgasse, close to the Bernehof and the Federal Palace, and punctually at half-past seven in the evening the *avant garde*, consisting of twenty students, bearing torches, turned the corner of the Spitalgasse, followed by the band and the rest of the students, all of whom held lighted torches in their hands, halted in front of the professors' residence. Here an enormous circle was formed, in the centre of which stood the officers with their drawn swords and splendid sashes, the flags and the band. Then, at a word of command from the senior officer, they begin to cheer lustily, and to call for Herr Professor Lücke, and Herr Professor Klebs, who were, of course, quite prepared for the occasion, and had their rooms brilliantly lit up in honour of the event. Throwing open the windows, the two professors appeared and bowed, after which there was more cheering. When silence was again restored, a student left the circle, and after bowing to the officers and his companions, he took off his cap and began a capital speech, which he delivered in good style, never hesitating for a moment, and frequently turning to the students when he was about to say anything complimentary, a hint

which they showed they understood by their cheers when he got to the end of his sentence. As the torches showed signs of going out fresh ones were used, and the whole street became lit up most brilliantly. In addition to the large number of students with their picturesque dresses, the windows and balconies of the houses on each side of the street were filled with people, while below there was an enormous crowd, whose faces showed how interested they were in the scene which was going on.

We may pass by the description of the student's eloquence and the replies of the professors, after which, with music and cheering, the procession reformed and went to the place appointed for the supper.

We must, however, quote the testimony of this writer as to the general character of the students of Berne. It is a cheering picture :—

> They work hard, their lectures beginning at six in summer, and seven in winter, and continuing throughout the day, with the exception of two hours for dinner. And they are not immoral. There are about 1,000 students altogether at the university, while the number of "unfortunates" is very small indeed. This latter fact is due in some measure to the strict police regulations, which are rigidly enforced, but still more, I think, to the circumstance that students are allowed to ask the daughters of respectable people to their balls. The young ladies go and return in charge of the students who have given them the invitation without any chaperon, and the confidence placed in the students is seldom or never abused, while they, in this way, gain an *entrée* into good society, which prevents their seeking amusements at the *cafés chantants*, or low music halls, which are such snares for French and English students, but which the students here, I am glad to say, show but little desire to frequent. The fees at the university are very moderate, and as many of the students lodge with private families they manage to cover all their ordinary expenses for about 1,500 francs, or 60*l.* per annum. To any one who wants to give his son a good medical education at a moderate cost, and at the same time to keep him free from the temptations of London or Paris, I can strongly say that he might do far worse than choose Berne.

◆

SCOTLAND.

Mr. Disraeli has intimated that, owing to other public engagements, he will be unable this year to deliver his Inaugural Address as Lord Rector of Glasgow University.

The report for last week indicates that there is no abatement of the small-pox epidemic in Edinburgh.

Edinburgh Royal Infirmary.—Sir Roundell Palmer is of opinion that, according to the meaning of the Infirmary Act of 1870, firms and companies are legally entitled to vote at the meetings of the contributors.

◆

Notes on Current Topics.

Prussic Acid under the Commune.

In connection with the meeting of Communist refugees, which was held in London on Monday evening,—*to celebrate the Proclamation of the Commune in Paris ;* we may cite the following evidence given before the Parliamentary Commission of Inquiry in to the Acts of the Insurrection of March 18, 1871 (just published by Baillière, Paris and London).

Deposition of Colonel Gaillard.—Do you know of any instruments intended to poison with Prussic acid, carried in a little india-rubber tube ?

Answer.—Yes ; it is the serpent's tooth, with all its appliances. There is a little spring to cause the venom to spurt, and make it penetrate the wound.

A Member.—I have seen the instrument ; it is an india-rubber ball, armed with a very short, sharp gold pin, that is the fang of the rattlesnake. When the needle is applied to the body, it presses the ball and the Prussic acid is carried by the needle into the wound.

Two young men were employed to manufacture two litres of this acid, with the condition that they should not be sent to the ramparts during the Commune.

It is said that 20,000 of these infernal instruments were made.

Certificates of Insanity.

It constantly happens that Medical men who are not engaged in asylums, experience great annoyance respecting the certificates they are called upon to fill up. We very often meet with instances where misapprehension of such certificates, or want of attention to the precision upon which the Commissioners insist, causes the certificate to be pronounced useless. It seems easy enough to those who are constantly filling up these forms, but those who are only occasionally called upon to do so find them very troublesome. We are glad therefore, to find that Mr. Hardwicke has just published "Plain Directions for Dealing with an Insane Patient," from the pen of Dr. J. M. Winn, who has had immense experience in the care and treatment of lunatics, and whose advice may be followed on this matter with implicit confidence. The directions are so plain, that it is almost impossible to mistake them, and we cordially recommend this little work as sure to be useful to all who feel any hesitation about the filling up of the certificates equired for an insane patient.

Rhinegau Champagne.

All champagne drinkers have heard of the Johannisberg Castle, but few know that within a radius of three or four miles quantities of good champagne are produced, that can be sold at a very low price. They may be glad to learn, that under the name of Rhinegau champagne, this produce is now being introduced into England by Messrs. F. T. Denyer and Co., of Regent street. We have tasted it and can speak favourably of its quality. It is a sound wine, with a fine flavour, and will not be likely to disagree with delicate stomachs. At two guineas a dozen it ought to find a rapid sale.

The Ophthalmological Congress.

The place of meeting of this important International Congress, has been changed from Berlin to London. The Royal College of Physicians has been generously placed at the disposal of the committee, in which building it is proposed to hold the preliminary meeting for arrangements on July 31st. The Congress will be held on the three following days, which it is hoped and expected will be a grand success. Mr. Critchett has been elected chairman, and Mr. Soelberg Wells, honorary secretary.

The Mediterranean.

Now that the Prince and Princess of Wales have gone to spend a little time in the sunny south, a few lines we have received from Dr. Proell, of Nice, respecting its climate will be interesting. He has spent many winters there, and passes the summer at Gastein. He says that, unfortunately, almost all Medical, and even non-medical men are of opinion that only patients with weak chests should be sent to Nice. At the word Nice everybody thinks of consumption. Whenever a chronic cough is heard Nice is recommended. This great humbug has lasted many years. But the world has now discovered the error, and a great reaction has set in. For some six years all consumptives have been sent to Mentone, as if its climate, position, and quietness would be the panacea of all those who suffer in the respiratory organs. From the one extreme the world runs to the opposite. Nice, he continues, has five different climates, as well as that of Mentone. But the different diseases of the kidneys, and their numerous consequences and forms, asthma, rheuma, gout, &c., should be sent to Nice, because kidney diseases, especially Bright's disease, are very rare among the inhabitants, whilst tuberculosis is frequent. The continual influence of the brilliant sun upon the skin delivers the kidneys from their vicarious action or double function, or increased, and therefore morbid energy. The great object of going to Nice is not *the heat*, which could be obtained at home, and better, where windows and doors shut better; *but the dryness of the air and streets*, the clearness of the sky, is the principal object, because all persons for whom exercise in the open air is the principal remedy could not have it in their homes. But in the south, and principally at Nice, whose air is as astringent, positive-electric, and vivifying as the thermal water of Gastein.

He then goes on to say, "To prove that I do speak *pro domo* because I am a physician at Nice, I may say that I never allow, when consulted, any young patient, from 15 to 45 years, who has an hereditary disposition to tuberculosis, to go to Nice, when the temper is sanguine or choleric, and his nerves are irritable, his mind never satisfied, difficult to be managed; because I see always bad results. Also I never send to Nice patients with dispositions to acute congestion of the brain or lungs. But I see the best cures from the climate of Nice in all phlegmatic or melancholy individuals, of calm and benevolent temper, without disposition to acute congestions to the head or chest. I saw excellent effects at Nice in persons worn out by too much fatigue of body, who overwork their mind or body; also the victims of mercury or iodine, or of too exaggerated hydropathic cures in advanced age. I found very good results in anæmic and chlorotic individuals, or those who have lost too much blood by wounds, or by operations, or by bleeding too often, or after metrorrhagia, &c. I send also scrofulous and rachitic children, and young people with disposition to tuberculosis from scrofula, and elderly individuals, where only the oil of the lamp of life is wanting. Chronic catarrh from relaxation of the fibre muscularis, or asthma from emphysema, has found miraculous effects. But in all these cases the choice of the position of the lodging must be determined by a conscientious Medical man, who knows Nice thorougly.

Analysis of Milk in New York.

Dr. Schweitzer, Assistant Professor in the School of Mines of Columbia College, New York, has had occasion to analyse a very large number of specimens of milk, gathered by the Sanitary Inspectors of the Board of Health, and never found any other adulteration than water. The popular impression that chalk, calves' brains, and similar unappetising impurities are added by milk dealers, appears to be erroneous.

The best specimens of condensed milk gave: water, 53·54; butter, 13·12; casein, 14·14; sugar, 16·30; ash, 2·60. In the preparation of the condensed milk, 430 quarts were condensed to 100, and the solid constituents increased from 12·55 to 46·46 per cent. These results appeared to warrant the suspicion that 378 quarts had been reduced to 100; but by making the correction, called for by the fact that the quart was a measure of volume while all the determinations were made by weight, the company were found to have actually started with 430 quarts to make 100 of the condensed article. The ashes of milk are rich in phosphates and alkalies.

Meeting of the International Ophthalmological Congress in London.

It having been decided by some of the leading members of the Ophthalmological Congress that the meeting which was to have been held in Berlin this year shall take place in London, a committee of the London Ophthalmologists has been formed to carry out this intention. They have decided to invite their *confrères* to assemble in London on Wednesday, July 31, 1872, for preliminary arrangements, at the Royal College of Physicians, Pall Mall, where the meetings of the Congress will be held on Thursday, Friday, and Saturday, August 1, 2, and 3.

Criminal Abortion.

The Medico-Legal Society of New York, at a recent meeting, received a report from the Committee on Criminal Abortion, which recommends a change in the law, so that the crime may be simply a felony without any specified denomination, and providing as a penalty *not less* than four years' imprisonment. The report was adopted, and a committee of responsible citizens appointed to wait on the Governor and urge the passage of such a law by the legislature. This change would give a judge the opportunity of sentencing such a villian as Rosenzweig to Sing Sing for life.

British Diplomas in Canada.

At the last meeting of the Canada Medical Council, the question, we are informed by the *Canada Lancet*, was raised by Dr. Dewar as to whether or not British diplomas were alone sufficient to entitle the holder to practice in Canada. After some discussion on the subject, it was resolved that the President be requested to communicate with Sir John A. McDonald, and obtain his opinion on the question. Accordingly, a week or two after the Council was prorogued, the President addressed the Colonial Premier on the subject, and received an immediate reply to the effect that, as Minister of Justice, the matter did not come within his jurisdiction, but that he would transmit the letter to the Hon. John Sandfield McDonald, the Colonial Attorney-General, who, in course of conversation, admitted that there was no question that in all civil matters the Legislature of Ontario was supreme, thereby settling, in the opinion of the *Canada Lancet*, the question that our British practitioners who have obtained their diploma subsequent to the passing of the Canada Medical Act must comply with the requisitions of the Colonial Medical Council.

Exemption of Chemists and Druggists from Jury Service.

THE trading chemists of England are prosecuting a movement for the introduction into a Bill promised recently by the Attorney-General, of clauses exempting them from jury service; and the representatives of the trade seem to entertain strong hopes of a favourable consideration of the proposal.
